In the clinical picture of this last case we have many an illustration of direct onslaught on the sympathetic, and what many would wrongly, I believe, term a reflex disturbance instead of a direct.

I presume, gentlemen, that many of us could recall almost innumerable instances of cases arising in our own practice illustrating the point which I have wished to bring out, that it is a clinical mistake to ascribe many symptoms of a disease entity to so-called reflex action, for thereby our diagnostic acumen is misled in a given case and we are thus prone to treat the spine or the brain even, when the ætiological factor is so often resident in the domain of that great vegetative, assimilative nerve without which there can be no vegetative life, without whose proper nervation there can be no sentient physicism. In closing, let me remind you that a practical guiding point in the determination of proper sympathetic nervation always is to be estimated by the behavior of the sphincters of the solar plexus, the head and front, I believe, of this nervous system; which may be found not alone in the rectum, but in the vagina, uterus, tubes, urethra, bladder, ureter, lips, eyes, stomach, in short, dominating all semiclosed cavities of the body. If the financial rating, health, and autonomy of a metropolis is properly measured and guarded by its sewage, none the less is it true that the same facts pertain, in the main, to the laws of the health of the body, that there may be proper physiological functioning of the same.

If your reader has unduly taxed your patience by the personal equation, he hopes to be forgiven, since he has always been profoundly interested in a subject which ought to be more thoroughly investigated and brought before professional minds.

With the hope that the matter may merit your intelligent criticism and provoke a thorough discussion, your reader thanks you all for the attention which you have been pleased to bestow.

## TRAUMATIC HÆMARTHROSIS OF THE KNEE JOINT.

By J. O'CONOR, M. A., M. D., B. CH., TRINITY COLLEGE, DUBLIN  
SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AIRES.

CASE I.—P. S., aged thirty years, sailor, admitted on the 2d of June last, suffering from stiffness and swelling of left knee joint.

*Previous History.*—While working on deck on February 3, 1895, he was knocked down by a sea, and immediately afterward his left knee was very much swollen

and painful. After a month's rest in his bunk, he was taken to a hospital in Hamburg, where, he said, they treated him for "congealed blood in the joint"; "with a hot probe they made an opening and squeezed the blood out." After six months he was discharged with an elastic bandage; he was unable to resume work for another two months, owing to the constant pain and swelling, and from that time until his admission into the British Hospital he could not flex the leg beyond a right angle.

On March 15, 1896, while crossing a plank from his ship to the wharf, the plank broke and he fell into the water, his left knee striking the curbstone as he fell; immediately afterward his mates and himself recognized that the kneecap was "split in two." He was taken to the nearest hospital, and the limb was placed in a box splint; this was not removed for seventeen days. After this, three consecutive plaster cases were applied, and thus the joint was kept immobile until June 1st. On this date he decided to come to Buenos Aires, for, he states, "my joint was useless, and I thought it better to clear from that place."

His condition, on admission into the British Hospital, was as follows: The left knee joint was considerably thickened and apparently distended; active movement absent; the patellar bursa was considerably enlarged, and any attempt at passive motion caused severe pain. On palpation a united vertical fracture of the patella was readily made out; there was a slight increase of local heat, but his body temperature was normal. These symptoms, along with the history, made the diagnosis pretty certain that dense adhesions had formed, most probably a quantity of organizing clot was still present in the articulation, and that the enlargement of the patellar bursa was due to effused blood.

On June 4th an incision was made into the joint; on opening the capsule no serum or blood was found, but when the right index finger was introduced six strong adhesions were encountered, firmly connecting the posterior surface of the patella to the femur; as a futile attempt was made to rupture them with the finger, a strong scissors was introduced and the adhesions were divided. A considerable amount of hemorrhage followed, so much so that it was thought advisable to irrigate with warm turpentine lotion; small sponges were introduced and direct pressure made. As some oozing continued, the joint was packed with iodoform gauze, and three "waiting" sutures were inserted. An incision was then made into the distended bursa and one ounce of dark blood evacuated. The cavity of the bursa was lined with numerous melon-seed bodies; these were removed with a Volkmann spoon, gauze packing applied, and the leg placed in a McIntyre splint.

*Second Day.*—Dressings removed. The gauze was so saturated with blood that it had evidently been converted into a plug, for when it was removed a quantity of blood escaped from the joint; irrigation with turpentine lotion, and a gauze drain inserted.

*Third Day.*—Dressed; oozing still continues; irrigation and drainage.

*Sixth Day.*—The joint was found quite dry.

*Ninth Day.*—The wound was closed by "waiting" sutures.

*Fifteenth Day.*—Splint removed and stitches taken out; the bursal wound was also healed; patient was ordered to commence active movement.

*Sixteenth Day.*—Allowed out of bed; he could flex the leg to a right angle.

*Eighteenth Day.*—He walked across the ward with-

out a stick, and by the thirtieth day he could run and kick and flex the leg, almost making the heel touch the nates.

*Fortieth Day.*—He walked out of the hospital without a limp, normal movement completely restored. A month later he reported that his limb was normal.

*CASE II.*—P. W. W., aged twenty-nine years, camp man; admitted into hospital on July 8th, suffering from painful distention of right knee joint.

While playing polo on July 5th he was run into, his opponent's horse's chest catching his right knee, and knocking over both him and his steed. On account of the severe pain he had to lie on the ground for some time, "but after a big lot of *caña* he was able to resume the game, finished the quarter, and managed to hit the deciding goal"; when play ceased he could not lift his right leg to dismount.

He was put to bed and, of course, had his knee rubbed with Elliman's embrocation, which increased the swelling, stiffness, and pain; however, he continued rubbing, but by the 8th of July things looked so bad that he came to Buenos Aires and entered the hospital.

On the 9th I aspirated the joint and found blood; he was immediately placed under chloroform and the usual incision made; three ounces of blood were evacuated, and the joint was irrigated with warm 1-in-2,000 corrosive sublimate, and gauze drain and "waiting" sutures inserted.

The third day the dressings were changed, a large quantity of synovial fluid escaping after the gauze was taken out; drain again inserted.

*Fifth Day.*—Again dressed, joint quite dry.

*Seventh Day.*—Gauze drain dispensed with; he flexed the leg through half a right angle.

*Twelfth Day.*—Wound closed.

*Seventeenth Day.*—Allowed out of bed, movement to a right angle.

*Twenty-first Day.*—Sutures removed. He could walk without crutches, movement almost normal. He was discharged cured on the twenty-fourth day.

A week later he reported that his limb was as strong as ever.

*CASE III.*—R. P., aged thirty-one years, camp man. On May 14th, while driving in a sulky, the horse bolted, and when the patient was jumping from the trap his left leg got caught between it and the wheel, the limb being severely wrenched. Immediately afterward he attempted to stand, but could not do so; he was taken home, put to bed, and had his knee rubbed with Elliman's embrocation; this treatment increased the pain and swelling. Next day hot fomentations were applied with some relief. On the fourth day he was taken to the nearest town and a doctor called in, who stated there was a fracture into left knee joint, and that a permanent stiff knee would be the result. The following day he was taken to Buenos Aires and admitted into the British Hospital. On examination the left knee was found greatly distended and very painful to touch; no crepitus elicited, as passive motion was impossible; heat well marked; a large extravasation of blood had taken place into the popliteal and calf regions; temperature, 99.5°.

On the following morning chloroform was administered, and an incision an inch and a half in length made parallel to the inner border of the patella; five ounces of blood and clots were evacuated from the joint. On digital examination no fracture was discovered; the cav-

ity was irrigated with warm 1-in-1,000 corrosive sublimate, in order to remove some adherent clots, iodoform gauze drains inserted into the synovial pouch, and three "waiting" sutures were introduced through the whole thickness of the incision.

*First Day.*—Dressings and drains removed, joint quite dry, temperature normal, gauze reinserted.

*Sixth Day.*—Sutures were drawn tight and the wound closed.

*Twenty-second Day.*—Splint was removed; active movement through an angle of sixty degrees.

*Thirtieth Day.*—He was allowed out of bed; movement through a right angle. He was discharged on the fiftieth day. He could now bear his weight on the limb and move the joint to a little more than a right angle. On the eightieth day he came to the hospital to report himself. He could walk briskly; movement almost normal; no pain; he informed us that he had been riding about the camp for the past fortnight without any inconvenience. He was ordered massage.

Up to the present time the treatment of this affection has been somewhat vague, doubtless due to the fact that the character of the effused fluid was often merely guessed at; consequently, many cases of hæmarthrosis were treated as if they had been collections of serum and synovia. The treatment adopted was a general one: absolute rest, ice-bags, strapping, and blisters; therefore it can not be wondered at that some of the patients remained with permanently damaged knees; for it is perfectly obvious that formation of adhesions must follow such treatment for effused blood, which, when once formed, are almost impossible to get properly rid of unless the joint is opened and the bleeding from the ruptured adhesions drained off. I think there are very few of us who have not, time after time, diagnosed such effusion as simple synovitis, and applied the orthodox expectant treatment, without precisely knowing whether we had to deal with a collection of blood, or of serum, or an excess of synovial fluid, or a combination of them all. This inexactitude in treatment was in great measure due to the septic idea that the knee joint was holy ground so far as a surgical instrument was concerned. As Listerism has altered that condition of things, I think there can be no practical reason why an aspirating needle should not be used in the majority of cases, as a mere diagnostic agent, in order to find out exactly what is the condition we are called on to cure. Without seeing the fluid we can not properly treat the case, nor can we give a correct prognosis. Possibly, in the near future, a development of the Roentgen rays may even render such a test unnecessary.

On consulting one of the best and most recent *Systems of Surgery* (Treves), I find the subject of hæmarthrosis is not even considered under a separate heading, mentioned only in the differential diagnosis of acute synovitis, and in all only some twenty lines are devoted to its signs, and nothing as to its treatment. This fact in itself suffices to show that it has not been looked on as of frequent occurrence, yet I feel per-

fectly certain that effusion of blood, following injuries to the knee joint, is much more common than is ordinarily supposed. It may be interesting to consider some of the methods adopted for the treatment of this lesion.

*Firstly.*—We have the expectant or absolute-rest plan. No doubt this has antiquity on its side, but I think little else but bad can be said of it, and the reasons of this opinion are so very obvious that it is unnecessary to waste valuable space by detailing them.

*Secondly.*—There are some who recommend massage and early movement, without any preliminary operation. If the teaching of Hilton is to be considered at all, such a practice as rubbing the surface of a painful and irritable joint, in order to help Nature to absorb blood, is as barbarous as it is unsurgical. Indeed, the patient, if left alone, would, in all probability, adopt this plan. By his consulting a doctor who believes in this method, he eventually gets something more, an introduction to the professional masseur, who immediately informs the client that he should have come to him "right away"; that "it will cost so much money and take so many months to loosen the strings and work the bones back into their places." It would be quite superfluous for me now to follow such a case to its conclusion, if it ever has one. During ten years' constant hospital experience I have had, I regret to say, many opportunities of seeing the results of such injudicious treatment, and I trust as our science advances such a method will be not only not practised but forgotten.

*Thirdly.*—Evacuation of the blood by puncture, supplemented by massage and early movement, is rather the fashion of the day. Quite recently I had the opportunity of reading in the *British Medical Journal* Mr. Barker's description of an operation for recent fractures of the patella. In this he admits that the removal of the effused blood is a most important matter, and in order to serve the object of this paper I will state how he proceeds to do it. With a narrow-bladed knife he makes two punctures, one above and the other below the patella; he then "squeezes" and "kneads" the joint, and by such manipulations professes to "effectually" empty it. "It is quite clear that this can be more completely effected at once through our punctures, and, in these aseptic days, quite as safely."

To any one accustomed to evacuate blood from joints by free incisions this must appear an uncertain if not an impossible task, for—

(1) There are some parts of the joint where squeezing and kneading can not possibly dislodge the coagulated blood.

(2) The joint has already received severe traumatism; to this the above-described manoeuvres are added, which doubtless only tend to increase the irritation of the already injured structures.

(3) The danger of blood gravitating back into the joint from the very punctures themselves. I have fre-

quently noted, on opening the knee joint, the vascularity of the cut tissues, necessitating some minutes' sponging or ligation of the bleeding points before opening the capsule; and

(4) The uncertainty that must attend any subcutaneous operation.

Mr. Barker, in another part of his paper, states: "Another most important measure to be adopted immediately after operation is massage; this is begun the day after operation and continued for a couple of weeks; the effect is to cause absorption of any blood left in the joint and the tissues around." I confess I was astonished to encounter this statement after the one mentioned above, for it is either a direct contradiction or else the terms "effectually done" and "completely effected at once" are misapplied.

Even with these two performances the job is not finished, for he states: "Now as to the adjustment of the fragments: Before the wire is introduced the operator takes each fragment between the finger and thumb of opposite hands; he then proceeds to rub the fractured surfaces one against the other; then, rubbing them from side to side, he is soon conscious he has dislodged all the blood from between them, or clot, or fibrous material, and that they grate one against the other like lumps of sugar." No doubt when the "sugar" feeling is obtained, blood and clots are most probably dislodged; but what becomes of bits of clot, fibrous material, and bone dust? As Mr. Barker does not state that squeezing and kneading delivers them through the puncture holes, I infer that he unwittingly converts the knee joint into a sort of surgical dust bin.

As I stated in a previous paper on this subject, I have often puzzled over the rationale of early movement and massage at a time when the joint structures are irritable and inflamed. Mr. Barker fully satisfies my curiosity when he confesses that they are used partly to get over imperfections in the operation; and I can thoroughly appreciate it would never do to give Nature a chance when bone dust, bits of blood clot, and fibrous material were left loose in the joint cavity.

I do not wish it to be understood that I for one moment advocate the abolition of massage and movement; on the contrary, I consider them most excellent measures in their season: that is, when the fragments have had time to unite, the irritation and inflammation of the joint structures have disappeared, and care has been taken that the principal cause of adhesions, blood, has been effectually removed. If the latter is not thoroughly done, I look on them as a species of brute-force surgery, with, as usual, a Nemesis in store for it. In order to bear this opinion out more fully, I can not do better than quote the last paragraph in Mr. Barker's paper: "It should be remembered that patients who have once broken their patella are liable, whether operated on or not, to attacks of synovitis on overexertion of the joint; with a little rest the condition is quite relieved. We can

hardly expect after so severe an injury as that which fractures the patella that there should be in all cases a complete re-establishment of the vasomotor balance in the circulation of the synovial membrane."

In those who have not had an operation I expect "nothing," but in those who have been operated on I fail to see, if a proper operation was carried out, why recurrent synovitis should take place. No doubt, the lack of the re-establishment of the vasomotor balance is a very pretty idea, but I should think rather a feeble scapegoat. I attribute such failures to the fact that with the *nimia diligentia* of meddlesome surgery, in the way of ill-timed massage and movement, combined with a faulty operation, the synovial membrane has never had a chance to return to its normal state. Instead, a chronic inflammation is set up, a fire left smoldering, necessitating only some overexertion to set it ablaze again.

It may seem a forlorn hope for any surgeon to attempt to stem the tide, the craze of the hour, but, as in everything else, reflection and reason ultimately gain the upper hand. The value of fads is impartially analyzed, their good points are retained and their bad ones cast aside, and doubtless time will strike the happy mean so far as massage and movement are concerned, in joint surgery.

At present it would really appear that the tendency of modern surgery is to absolutely ignore physiological repair, for, in every medical paper one opens, some new ambulatory treatment for fractures or joint injuries may be seen vaunted; the idea of pausing to consider if our methods are consistent with physiology would appear mere waste of time. Yet how refreshing it is to occasionally meet with an article like that written by Mr. Stanmore Bishop, *The Eye as a Joint*. I have not yet seen his question answered: "If you dare not rub an inflamed eye, why do you presume to rub an inflamed joint?" Surely the advocates of early massage can give a better answer than that they do so in order that atrophy of muscle and bone may not ensue, for atrophy is a natural physiological consequence to the rest that is requisite for physiological repair.

In conclusion, the treatment I wish to bring under the notice of the profession is:

1. In cases of effusion into the knee joint an aspirating needle should be introduced in order to arrive at a correct diagnosis.

2. If blood is present, an incision should immediately be made into the synovial pouch, and every particle of blood and clot removed; in case of fracture into the joint, the fragments should be examined, and, if necessary, reduced and fixed.

3. A gauze drain should be inserted for a few days in order to make certain that no further reaccumulation shall take place, and when it is evident that there is no further danger of this occurring the external wound should be closed by "waiting" sutures.

4. When union is sufficiently firm, active movement should be encouraged, and when this can be painlessly executed, then, and then only, is massage a most useful adjunct in restoring the muscles to their normal condition.

#### A CASE OF

### BIFID UVULA WITH DEGENERACY.

By LEWIS S. SOMERS, M.D.,

PHILADELPHIA.

ABNORMITIES of the soft palate, and especially that portion of it denominated the uvula, are more or less frequently seen in examining a large number of cases suffering from nose or throat affections. Berens, in an investigation of three thousand throats, found the uvula abnormal in eighty-four cases, fourteen of which were deeply cleft. In a considerable proportion of the so-called deformities of the uvula it is extremely difficult to definitely ascertain whether the abnormality present is due to previous disease or is a true congenital deformity—as, for instance, twisting of the uvula to either side of the median line: in these cases it is almost impossible to say conclusively that the defect is congenital. In marked abnormalities, such as cleft or bifid uvula, the distinction becomes one of ease, as there is no known disease that can exactly split the uvula up to the hard palate in the median line.

In conjunction with marked deformity of the uvula, other mental or physical malformations may be present in a considerable percentage of the cases; this seems to be especially marked in neurasthenic subjects. Dr. Charles L. Dana has lately made a study of the uvula in the various forms of degeneracy, and with results that show this portion of the organism to be defective, either as regards the shape or innervation, in very nearly fifty per cent. of the cases examined. As this subject has but recently been thoroughly studied, the following case is reported, not that any conclusions of value can be drawn from one case, but because the deformity of the uvula and the mental degeneracy were so manifest:

The history of the patient is as follows: G. M., male, aged eleven years; was admitted to the clinic of the Union Mission Hospital for chronic otitis media suppurativa. The boy's mental and physical condition were so characteristic of degeneration that the fauces were immediately examined for abnormalities, and the presence of a cleft or bifid uvula was ascertained.

*Family History.*—Father, mother, and two brothers well, and are all bright and intelligent; one sister dead, the mother giving an indefinite history of a "swelling" on the side of her neck which was supposed to have choked her. One brother died with symptoms of hydrocephalus.

*Personal History.*—Born at term; labor was normal, and without the use of instruments. He has suffered no injury to his head. At birth it was noticed that the head was small and compact, the fontanelles being smaller and pulsating more than is usually the case.

Was breast-fed and healthy until three months of age, when he suffered from a severe attack of cholera infantum, from which he never completely recovered his previous health. At nineteen months he had a very severe attack of measles, followed by a suppurating otitis, which has continued at irregular intervals until the present time. He has had no other acute illness, except some digestive troubles during his seventh year. He began to talk at two years and did not walk until he was three. His mother volunteered the information that he had always had a small head. Does very poorly at school, especially in reading and spelling, but is better in arithmetic, although far behind the boys of his own age. He has been going to school since his seventh year.

Understands and expresses a desire when he wishes to empty his bowels and bladder, but if he has to wait is not able to control them. Is not destructive, and expresses a desire to play with other children, and does not annoy them. His general health is fairly good, although he has always been less developed, physically and mentally, than the other children of the family. In eating soft food, as bread, he appears to suck it, and allows the saliva to disintegrate it rather than chew it; he will chew bread naturally when told to. Hard substances, as meat, he eats naturally. He is obedient, and seems to know all things which are told him, although his memory is very poor.

The general appearance of the boy is that of a child undersized for his age, slender in build, and with a facial expression characteristic of deficient mental faculties. His hearing has been gradually becoming impaired during the past two years, although whispered voices are readily responded to, all the change in audition noticeable being a slight diminution in hearing for the watch. His left ear is now practically normal, while the right still suppurates profusely, with evidence of necrosis of bone and the presence of aural polypi.

Examination of the fauces showed a moderate degree of hypertrophic inflammation of the posterior pharyngeal wall, without the presence of adenoid tissue. The uvula was cleft exactly in the median line up to the hard palate, which was moderately Gothic in character. Each half of the uvula seemed to have a separate muscular development, as the individual halves could be separated, although palatal motion was irregular and innervation was below the normal. Other than the cleft uvula, the soft palate presented nothing abnormal, no evidence of any previous diseased state existing. Instead of bifid the word double would more accurately describe the uvula in this case. In the normal uvula the azygos muscle consists of two distinct sets of fibres situated parallel to each other, but acting as one muscle; in this boy the intermuscular tissue, being one of the points of deficient development, was absent, therefore leaving the azygos muscles separated from one another, and each muscular body acting more or less independently.

A twisted or sharply bent position of the uvula is a frequent accompaniment of long-standing nasopharyngeal catarrh, especially if the tonsils have undergone much alteration. Diseases of the nerves or muscles of the soft palate are responsible for a small number of cases seen, but a twisted or acutely bent uvula usually indicates some previous nasopharyngeal inflammation. Defective innervation of the soft palate is frequently as-

sociated with chronic nasopharyngeal catarrh, and then seems to bear no relation to inferior or incomplete nervous development.

3554 NORTH BROAD STREET.

## Therapeutical Notes.

**The Treatment of Pityriasis Capitis.**—Gaucher (*Therapeutische Wochenschrift*, October 25, 1896) says that there are three indications to be fulfilled: 1. The removal of fatty matter and epidermal products by solvent washes. 2. The induction of a change in the skin. 3. Stimulation of the skin to replace the lost hair as far as possible.

The first of these indications may be met by the use of a 5- to 8-to-100 solution of sodium bicarbonate or this solution:

R Sodium borate.....	10 parts;
Ether.....	15 "
Distilled water.....	200 "

Better still is a mixture of equal parts of alcohol and decoction of quillaia bark.

The proper action of the skin may be brought about by inunction with a ten-per-cent. sulphur ointment. Instead of this, the following may be used:

R Corrosive sublimate.....	3 grains;
Chloral hydrate.....	60 "
Resorcin.....	30 "
Alcohol.....	300 "

M. If the skin is very dry, a drachm and a half of castor oil may be added.

Stimulating washes are to be used in the conclusion of the treatment, such as this:

R Tincture of cinchona.....	25 parts;
Tincture of cantharides.....	5 to 50 "
Tincture of benzoin.....	10 "
Spirit of lavender.....	20 "
Alcohol.....	125 "

M. If there is much dryness, the branny scales may be removed by bathing with salt and water or with a five-per-cent. solution of salicylic acid or a one-per-cent. solution of corrosive sublimate.

**Cocaine in the Treatment of Salivary Fistula.**—Guerra (*Annali di medicina navale*, 1896; *Deutsche Medizinische Zeitung*, October 22, 1896) relates the case of a soldier who had received a wound implicating Stenson's duct and the parotid gland, which had left a fistula that proved rebellious to treatment. Finally he painted the whole parotid region with equal parts of glycerin and a five-per-cent. solution of cocaine in water, and within a very few days the flow of saliva subsided. At the same time the wound was treated with the galvanocautery, and it healed in a few weeks. The author imputes the effect of the cocaine to its vaso-constrictor action, in consequence of which less blood was carried to the acini of the gland and less saliva was secreted.

**Nux Vomica in the Treatment of Psoriasis.**—Luton (*Belgique médicale*, 1896, No. 33; *Wiener klinische Rundschau*, October 25, 1896) employs extract of nux vomica in stubborn cases in which arsenic has been of no service. He gives three quarters of a grain daily, and at the same time prescribes effervescent baths and the application of a 1-to-1,000 ointment of corrosive sublimate and vaseline.

THE  
NEW YORK MEDICAL JOURNAL.

*A Weekly Review of Medicine.*

Published by  
D. APPLETON & Co.

Edited by  
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, NOVEMBER 21, 1896.

THE TREATMENT OF TUBERCULOUS DISEASE WITH  
MARAGLIANO'S SERUM.

THE *Centralblatt für innere Medizin* for October 24th gives abstracts of several recent articles bearing upon this subject. The first article, by Dr. Maragliano himself, appeared in the *Presse médicale*. In that article the author gives a brief account of how the serum is produced. In the preparation of a product analogous to tuberculin, the cultures are heated to 212° F., and then passed through a Chamberland filter; in that of another product, the cultures are not heated, but are concentrated at a temperature of 86° F. The first contains bacterial proteins; the second, bacterial toxins. As they are in many respects antagonistic in their action, Maragliano attaches great importance to mixing them. When the animals (dogs, horses, and asses) that are to yield the curative serum have by repeated inoculation been rendered proof against injections of highly toxic material, as well as against inoculations with tubercle-bacillus cultures that would kill unprotected animals, they are allowed to go for three or four weeks without further inoculations; then the serum is obtained from them and prepared by the ordinary methods. It contains specific antitoxins, and in man a cubic centimetre of it will neutralize an amount of tuberculin capable of giving rise to reaction.

In the next article, from the *Riforma medica*, Dr. De Renzi, of Naples, gives his experience with the treatment in twenty-two cases. Like his colleagues Dr. Bruschini and Dr. Boeri, Dr. De Renzi finds that the injections do not give rise to any important unpleasant result; swelling of the lymphatic glands may betoken a favorable reaction. In general, the appetite increases and a sense of well-being sets in. In some patients the tuberculous process is brought to a standstill; in others progressive improvement shows itself. The peculiar curative action of the serum occurs gradually and unnoticeably; it is most striking when compared with that of other measures intended for the cure of the disease. The cure can not be hastened by increasing the dose. The best results are obtained in cases of circumscribed and uncomplicated tuberculosis without much fever.

The third article shows how great a degree of pallia-

tion may be afforded even in hopeless cases. It is by Dr. Régnier, and appeared in the *Progrès médical*. One of the three cases reported was of that character, but even as the patient drifted along to the inevitable fatal termination his cough was diminished almost to the point of disappearance; the local phenomena, especially the crepitant râles, subsided; no extension of the morbid process could be detected; the sputa, from being massed and nummular, became more mucous in character; the night sweats came to an end; and the appetite and strength returned. Such efficiency of the serum in the palliative treatment of hopeless cases is not only a boon in itself, but a sure token apparently of the curative power of the treatment in cases in which, given a cessation of the progress of the tuberculous process, the lungs have not been so seriously injured that their repair is unattainable. Surely this is a substantial advance in the struggle against pulmonary consumption.

SILVER AS A THERAPEUTIC AGENT.

It is not long since we gave our readers an account of the experience of Dr. B. Crédé, of Dresden, in the use of silver and some of its salts in the treatment of wounds and of certain morbid processes. In a recent communication (*Centralblatt für Chirurgie*, October 24, 1896) he gives his further observation of the employment of silver, including that of about nineteen hundred cases, which, he says, quite substantiates his earlier conclusions.

He sums up his method of treating wounds as follows: Whether they are to be closed or to remain open, he covers them with silver gauze and dusts itrol (silver citrate) over any punctures that may be found. This gauze, containing metallic silver in a state of the very finest division, he says is absolutely unirritating and may be sterilized, but that he does not consider necessary. It becomes antiseptic as soon as morbid germs attack the wound, for the lactic acid which the germs produce unites with the silver to form the lactate, which is an energetic antiseptic. He cleanses the wounds with soap and water and a brush, applies ether to the surrounding parts, and rinses the whole with boiled water. If portions of tissue are almost completely separated, he removes them, but leaves large undermined flaps alone, also all fissures, opened joints, etc., and powders the surface of the wound lightly with itrol. If inflammation has already set in, he employs a water dressing for a few days; if not, he applies the silver gauze, lays cotton over it, and puts the injured limb at rest in a secure attitude. If the dressing becomes partially soiled by the oozing of blood and serum, he seeks

to promote drying by putting on more cotton, more for the sake of appearances than for anything else. If the discharge is very great, he renews the upper layers of the dressing. He does not dread the access of air to the wound, so great is his trust in the protection afforded against infection. If morbid germs have been forced into the recesses of the wound, they can not give rise to anything worse than an abscess.

For gargles, mouth-washes, and the like, actol or itrol may be used in the proportion of 1 to 4,000 or from that down to 8,000, although stronger solutions do not irritate. These silver salts stain the skin, but the stains are readily removed with a solution of one part of corrosive sublimate and twenty-five parts of sodium chloride in two thousand parts of water. In surgical infections, actol may be used subcutaneously. In erysipelas, the amount to be given daily ranges from seven to twenty-two grains, but the solution should not be stronger than one to two hundred, otherwise coagula of albumin will form and stop the remedy from getting into the circulation.

### MINOR PARAGRAPHS.

#### ARTIFICIAL SERUM AS A HÆMOSTATIC.

DR. LE CLERC (*Revue internationale de médecine et de chirurgie*, 1896, No. 11; *Centralblatt für Gynäkologie*, November 7, 1896) relates the case of a woman who lost a great deal of blood during her third pregnancy and with its termination in abortion. Neither curetting of the uterus with subsequent tamponing nor the use of drugs served to check the hæmorrhage, and her condition became critical, as was shown by her shallow breathing and the imperceptibility of her pulse. In this emergency the author injected about forty cubic centimetres of artificial serum (a solution of a drachm and a half of sodium chloride and two drachms of sodium sulphate in a quart of distilled water) into the basilic vein and, in addition, rather more than eight ounces of the same solution under the skin of the thigh. The activity of the heart and of the respiration was soon regained, the uterine hæmorrhage ceased definitively, and the patient recovered with striking rapidity. The author accounts for the hæmostatic effect of the injections by their stimulant action on the vasoconstrictor nerves.

#### ITEMS.

**The Brooklyn Medical Society.**—At the last monthly meeting, on Friday evening, the 26th inst., the following papers were to be read: Remarks on the Therapeutics of Gastric Diseases, by Dr. Jacob Fuhs, and The Results obtained by Double Tenotomy in a Case of Talipes Equinus, by Dr. F. C. Winter.

**Changes of Address.**—Dr. Russell Bellamy, to No. 152 West Fifty-seventh Street, New York; Dr. F. Tilden Brown (temporarily), to No. 22 East Fifty-sixth Street, New York; Dr. John Milton Holt, to No. 65 South Tenth Street, Brooklyn; Dr. A. M. Lesser, to No. 19 East Sixty-first Street, New York.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 17, 1896:

DISEASES.	Week ending Nov. 10.		Week ending Nov. 17.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	22	2	36	6
Scarlet fever.....	91	4	77	6
Cerebro-spinal meningitis....	1	1	1	0
Measles.....	62	3	63	3
Diphtheria.....	213	27	185	28
Tuberculosis.....	161	88	110	84

**The Roosevelt Hospital.**—A training school for nurses has been opened, and the pupils are to be quartered on the third and fourth floors of a new building called the private patients' pavilion.

**The New York Society for the Relief of Widows and Orphans of Medical Men** held its annual meeting and election on Wednesday evening, November 18th.

**The Society of Medical Jurisprudence.**—At the last regular meeting, on Monday evening, the 9th inst., Mr. Charles Bulkley Hubbell was to read a paper entitled The Obligation of the State in its Relation to the Health of the Child.

**The Death of Professor Lewin, of Berlin,** is announced to have taken place on November 2d. He was seventy-six years old.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending November 14, 1896:*

LA MOTTE, H., Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Virginia, and ordered to treatment at the Naval Hospital, Philadelphia.

MARSTELLER, E. H., Surgeon. Detached from the United States Steamer St. Mary's, ordered home, and placed on waiting orders.

WHITING, R., Surgeon. Ordered to the United States Steamer St. Mary's.

#### Society Meetings for the Coming Week:

MONDAY, November 23d: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, November 24th: New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, November 25th: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Medical Societies of the Counties of Albany and Tompkins (semiannual), N. Y.; Auburn, N. Y., City Medical Association; Philadelphia County Medical Society; Berkshire, Massachusetts, District Medical Society (Pittsfield).

THURSDAY, November 26th: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; New York Celtic Medical Society; Brooklyn Pathological Society; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.

FRIDAY, November 27th: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society; St. Louis Academy of Medical and Surgical Sciences; Cleveland Medical Society.

SATURDAY, November 28th: New York Medical and Surgical Society (private); St. Louis Medical Society.

## OBITUARY NOTES.

**Thomas H. Burchard, M.D.**, who died at his home, in New York, on Saturday, November 14th, in the forty-eighth year of his age, had been in ill health for a number of months, but in the summer it was supposed that he had almost wholly recovered, and this supposition seemed amply warranted by his robust appearance and his activity and cheerfulness. The hopes for him entertained by his friends were, however, destined not to be realized. The end came somewhat suddenly. Dr. Burchard seemed the embodiment of manly energy, with an unusual capacity for work, and appeared equipped for a long life of activity. He was a practitioner of more than ordinary acquirements, and, more than that, he was an open-hearted, generous, lovable man, one that will be sadly missed by those who knew him.

**Gustavus A. Sabine, M.D.**—Until within a short time before his death, at an advanced age, Dr. Sabine was a busy practitioner in New York, known and esteemed by almost every member of the medical profession here. He was a physician of much acumen and a genial man. He was an Englishman by birth, but almost the whole of his professional life was spent in New York. He did a general practice, but made obstetrics a prominent part of his work. In the early part of his career in New York he was connected with the late Dr. Willard Parker, and it is said that he first suggested to that eminent surgeon the feasibility of an operation for perityphlitic abscess. He was the father of the late Dr. Thomas T. Sabine. Dr. Sabine's memory will long be cherished in this community.

## Births, Marriages, and Deaths.

### Born.

**JOHNSON.**—In Augusta, Maine, on Tuesday, November 3d, to Dr. and Mrs. Wellington Johnson, a son.

### Married.

**BALDWIN—SHEPARD.**—In Newark, New Jersey, on Wednesday, November 11th, Dr. Edward Hill Baldwin and Miss Rosalind Grover Shepard.

**BLUMER—HENICAN.**—In New Orleans, on Thursday, November 12th, Dr. William Blumer, of Pensacola, Florida, and Miss Margaret Henican.

**CHITTERLING—PAGE.**—In New York, on Wednesday, November 11th, Dr. Nelson M. Chitterling, of Glen Ridge, New Jersey, and Miss Jennie Page.

**COMSTOCK—PORTER.**—In Montclair, New Jersey, on Thursday, November 12th, Dr. Seth Cook Comstock, of New York, and Miss Bertha Treadwell Porter.

**CONGDON—RAYMOND.**—In Brooklyn, on Thursday, November 12th, Mr. Ernest Wilfrid Congdon and Miss Mamie Gardiner Raymond, daughter of Dr. Joseph H. Raymond.

**KEELS—REMBERT.**—In Hagood, South Carolina, on Wednesday, November 11th, Mr. Ezekiel Keels and Miss Helen Rembert, daughter of Dr. Edward J. Rembert, of Rembert, South Carolina.

**MAYBANK—RHETT.**—In Charleston, South Carolina, on Thursday, November 5th, Dr. Joseph Maybank and Miss Harriet Lowndes Rhett.

**SHRADY—MOORE.**—In New York, on Wednesday, November 18th, Mr. Henry Merwin Shradly, son of Dr. George F. Shradly, and Miss Harrie Elbridge Moore.

**UNDERHILL—LELLMAN.**—In New York, on Wednesday, November 18th, Mr. Frederick Edgar Underhill and Miss Hildegard E. Lellman, daughter of Dr. Carl H. Lellman.

**WENDE—TUCKER.**—In Buffalo, on Monday, November 16th, Dr. Grover William Wendé and Miss Mary Graham Tucker.

### Died.

**ADAMS.**—In Brunswick, Maine, on Saturday, October 3d, Dr. M. Vinton Adams.

**BEEBE.**—In Alford, Massachusetts, on Tuesday, October 20th, Dr. Richard Beebe.

**BURCHARD.**—In New York, on Saturday, November 14th, Dr. Thomas H. Burchard, in the forty-eighth year of his age.

**GRAY.**—In Bastrop, Louisiana, on Monday, November 9th, Dr. Frederick C. Gray, aged seventy-three years.

**HITCHCOCK.**—In Rockland, Maine, on Monday, October 26th, Dr. Francis E. Hitchcock, aged forty-nine years.

**HOLYOKE.**—In Boston, on Friday, November 6th, Dr. William Cooke Holyoke, aged fifty-four years.

**LAMBREMONT.**—In Convent, Louisiana, on Wednesday, November 11th, Dr. P. S. Lambremont.

**McLAURIN.**—In Shreveport, Louisiana, on Thursday, November 12th, Dr. Duncan McLaurin.

**NOTT.**—In Beville, Texas, on Friday, November 13th, Dr. Henry J. Nott, aged sixty-nine years.

**O'BRIEN.**—In Troy, N. Y., on Saturday, November 14th, Dr. Francis J. O'Brien, in the thirty-ninth year of his age.

**OLIVER.**—In Ruston, Alabama, on Tuesday, November 10th, Mrs. Jessie A. Oliver, wife of Dr. Christopher C. Oliver, of Shelby, Alabama.

**SABINE.**—In New York, on Tuesday, November 17th, Dr. Gustavus A. Sabine, in the eighty-eighth year of his age.

**WELLINGTON.**—In Cambridgeport, Massachusetts, on Tuesday, October 27th, Dr. William W. Wellington, in the eighty-third year of his age.

## Letters to the Editor.

### PARALYSIS FROM MALARIAL FEVER.

DIRIAMBA, NICARAGUA, September 29, 1896.

To the Editor of the New York Medical Journal:

SIR: I wish to report a case of paralysis from malarial fever. The patient is a little girl, aged three years, whose previous history is good. Her parents have been healthy, never suffered from syphilis or rheumatism, and there has never been a case of paralysis among their near relatives.

She was taken with remittent fever, for the relief of which emetics and purges were the only drugs administered. On the twentieth day of her illness her mother was surprised to find her motionless in bed and unable to speak, in which state she remained for about twelve days, when she began to move the left arm quite freely; subsequently the fever disappeared and the little patient began to improve without any medical treatment, and continued to improve until about the sixteenth day, when she was brought to me with the following symptoms:

She could not stand, although while sitting down she could move the limbs around. She bore an idiotic expression and there was slight facial paralysis of the right side only, with aphasia; the left arm and hand were very weak in all their movements; the right ones more so, with complete paralysis of the extensores carpi et digitorum. The patellar reflexes were much diminished, and sensation was unaltered all over the body. There was no manifest visceral derangement.

She was put on the use of quinine and strychnine, and has been under that treatment for three weeks. At present she comes walking, with a bright expression, making efforts, though yet futile, to articulate words. Her left arm performs normal movements, the facial paralysis has disappeared, and the extensors of the right hand (previously paralyzed) are beginning to resume their function.

Judging from her rapid uninterrupted progress, I

think we may prognosticate a complete cure, within a month, by an antiperiodic treatment.

J. Y. GONZÁLEZ, M. D.

#### UNDUE HASTE TO EMBALM THE DEAD.

712 MADISON AVENUE, November 16, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In the *Journal* of November 14th you have given your approval to certain changes in the form of death certificates in New York city which are proposed by President Wilson and Commissioner Fowler. Permit me to call attention to a very important item which should be incorporated in that part which goes under the heading "To undertakers."

I refer to the very hasty and quite unwarrantable use of embalming fluid and processes before the certificate of death has been made out by the attending physician, and even before he has been called upon to pronounce the patient dead. Twice within the year this hasty work has interfered with post-mortems, which I very much desired and which the relatives did not oppose. It is quite evident, too, that much more serious harm might arise in a case where there had arisen a suspicion of poisoning.

It seems to me, therefore, that undertakers should be especially enjoined not to embalm or take any steps incompatible with life until the physician has made out his certificate. It might be well also to make a time limit, before which, and after supposed death, no such measures should be taken.

I think you will be doing the profession a favor and forwarding the ends of justice if you will call the attention of the health authorities to this matter.

S. S. JONES, M. D.

#### ANTIPYRINE AND CALOMEL.

238 EAST 105TH STREET, NEW YORK, November 9, 1896.

To the Editor of the *New York Medical Journal*:

SIR: In glancing over the column of Therapeutic Notes in your latest issue of the *Journal*, my attention was attracted to the article entitled *Incompatibility of Antipyrine and Calomel*. In this Dr. H. Werner is quoted as cautioning the medical fraternity against the simultaneous exhibition of these drugs, urging as a reason the dangerously large amount of bichloride engendered by the chemical interaction of these medicaments. To the latter assertion, in all probability based on laboratory experiment, certainly not on clinical observation, practical experience with the remedies in question enables me to take most emphatic exception.

During the past three years I have frequently and repeatedly prescribed these drugs, to be administered together, without the slightest untoward effect. On the contrary, the results obtained have been decidedly gratifying, the temperature yielding more promptly to this than to any antipyretic remedy in our armamentarium, with a corresponding amelioration in the condition. A fact worthy of note in this connection is that the reduction is of a more permanent character than that following the employment of any of the coal-tar products alone.

This combination—i. e., antipyrine and calomel—I have used in a rather extended list of ailments, mainly, however, in children ranging from six months to three years. The doses prescribed have been from half a grain to three grains of antipyrine and from a twelfth

to a quarter of a grain of calomel given every two hours, sugar of milk acting as a corrective and excipient.

My observation of the effect produced by this combination on these susceptible organisms—in which the toxic effect of the bichloride would be rapidly evinced, were the latter present—leads me to conclude that neither drug recognizes, so to speak, the presence of the other in the economy. The antipyrine produces its usual antipyretic effect, accompanied by a sedative action on the centres of the brain and spinal cord, while the mild chloride supplements this action by eliminating effete materials from the circulating fluid, and through stimulation of the hepatic functions fortifies the system against the onslaughts of the disease, at the same time reducing to a minimum the possible depressing effects of the drug with which it is associated.

Ergo, antipyrine and calomel, prescribed simultaneously in proper medicinal doses, constitute, to my mind, a perfectly safe, efficient, even an ideal febrifuge.

BERNARD S. ROSENAU, M. D.

#### Proceedings of Societies.

##### MEDICAL SOCIETY OF LONDON.

Meeting of May 11, 1896.

The President, Sir CRICHTON BROWNE, M. D., F. R. S., in the Chair.

**The Connection of Intestinal Autotoxis with Certain Common Forms of Insanity.**—DR. ALLAN McLANE HAMILTON, of New York, read a paper with this title. (See pages 576 and 643.)

THE PRESIDENT congratulated the society upon the presence of so distinguished an authority as the author, a courtesy which he hoped would be reciprocated by the reading of a paper by an Englishman before the Academy of Medicine of New York at some future date. He recalled the excellent work done by the author during the last twenty years in the department of medicine with which he himself was most associated. The paper opened out new and original ground, though he supposed the author himself would admit that much of it was speculative. Many of his conclusions, indeed, could not at present be implicitly received and accepted, and autotoxis would not drive out of the field all the older methods of dealing with this class of cases, though it might prove a valuable help in treatment. He recalled the fact that Dr. Lauder Brunton had pointed out the resemblance which exists between the languor associated with indigestion and the effects of curare poisoning, and that he had suggested that these symptoms might be due to the absorption of poisonous matter from the intestines, probably of the nature of ptomaines. It was only necessary to suppose an excessive production of these ptomaines or their imperfect destruction by the liver, which, under ordinary circumstances, prevented them reaching the circulation, to understand that this failure to protect might have far-reaching consequences. They had only to imagine this to see that in the long run a condition might be engendered which might culminate in melancholia with stupor, evidently strictly analogous to the autotoxis to which the author had invited their attention. That the production of these bodies in the intestine might be enormously increased in certain states had been clearly demonstrated, and he himself was inclined to believe that their presence in excess

in cases of intestinal catarrh might readily give rise to the mental consequences associated with this condition. He pointed out that there was a well-known type of hypochondriacal melancholia associated with catarrh of the transverse and ascending colon in which the mental characteristics were out of proportion with the lesions, cases in which there was no family history, and the symptoms yielded readily to a visit to Carlsbad or Marienbad. He had often thought that the symptoms in these cases might be due to excessive production of ptomaines in the intestine or to their imperfect destruction by the diseased liver. The possibility of putrefactive changes in the intestine and the consequent production of ptomaines were, of course, very great and very varied. He mentioned that, according to Mr. J. Murray, of the British Museum, there were 128 genera of microbes and 169 fungi which thrived and flourished in faecal matter; many of them were peculiar to particular kinds of faeces, 45 to the horse, 35 to the dog, 28 were peculiar to birds, and 21 to the faeces of man. It was clear, therefore, that faeces afforded a very favorable and congenial nidus for fungoid and bacterial growth, and any change in the physical contents of the lower bowel or any change in their environment interfering with the fungoid struggle for existence, by giving advantage to one variety, might allow of the production of an excessive amount of certain poisons, followed by symptoms of poisoning. He asked whether the brain itself might not provide poisons, seeing that poisonous ptomaines had been proved to develop in cerebral matter after death, and it was possible that under certain conditions of malnutrition similar products might be produced at an earlier period. Muscles were known to develop various alkaloids during life which might, under particular circumstances, even determine a fatal effect. It was also worthy of consideration whether the epileptiform seizures which checkered the course of the later stages of general paralysis might not be due to autotoxis. There was a gradual degradation of nutrition and possibly incipient decomposition of albuminous tissues which might produce substances acting as poisons on the nerve cells, producing a special train of symptoms along with a rise of temperature. Selbing had shown that ptomaine was found in the general paralytic and in pneumonia, and one was familiar with the fact that washing out of the lower bowel was often the means of arresting the epileptiform attacks which characterized the later stages of general paralysis. He supposed the author would admit that the subject was at present better fitted for the laboratory than for academical discussion. His title, indeed, was very comprehensive, for it might be made to include all forms of moral and intellectual auto-intoxication, a phenomenon which resulted from undue egotism and the concentration of the energies on selfish or degrading objects. Ideal microbes and emotional ptomaines would lead them too far afield, and he would, therefore, not enter upon their discussion.

Dr. HAIG said it was now nearly eight years since he had first called attention to the presence of an excess of uric acid in the urine of cases of mental depression and of epileptic convulsions, etc., and he was still of the opinion that the symptoms in such diseases, now referred by some to intestinal putrefaction, were really due to the presence of an excess of uric acid in the blood. The uric acid altered the circulation throughout the whole body; the altered circulation in the brain accounted for the mental symptoms, and that in the stomach and intestines caused putrefaction to take the place

of digestion. He had been much interested in what the author had said about the beneficial effects obtained by the use of calomel, because calomel cleared the blood of uric acid. It would, therefore, tend to prevent the modification of the intestinal circulation, which was the cause of the putrefaction. Salicylate of sodium also cleared the blood of uric acid and so prevented its exerting its usual effects. In one of the cases on which the author had laid considerable stress, he noticed that the patient got better when the regimen was changed, but they had not only changed the diet but given antiseptics and washed out the intestines as well. He had laid great stress upon these things but had said little about the diet. His own idea was that they gave far too much nitrogenous food, and when this was discontinued and the introduction of uric acid put a stop to, the patient got well. Many patients suffering from mental disease had been cured simply by diet, without any attention being paid to intestinal putrefaction. The points about uric acid which he wished specially to bring to the notice of those interested in mental diseases were the well-marked clinical signs of its excess in the blood—viz., high blood pressure and scanty urine. In some of the author's cases he had noticed scanty urine, and this, no doubt, meant an abundance of uric acid in the blood. If they controlled that either by diet or by drugs they would control the circulation and the mental disease.

Dr. ANDRIEZEN said there was no doubt that one source of the poisons which generated insanity was inside the body during life (poisons of endogenous origin). From bacteriological study we knew that actual toxins could be obtained from the cultures of various pathogenic bacilli—such as those of cholera, typhoid, tetanus, etc., which, injected into the body of man or animals, produced the special and characteristic phenomena of the disease in question (Koch, Pouchet, Brieger, and others' researches). Referring to the intestinal poisons arising from constipation, it was well known that in those accustomed to a *daily* evacuation of their bowels a comparative slight delay (a few hours to one day) was sufficient to bring about headache and depression of spirits, which immediately passed off when the bowels were relieved. The mere retention of faecal matter, even for a few hours, permitted of the passage of a certain quantity of poison into the blood. He found it difficult to explain this circumstance on the hypothesis of uric-acid formation. An excess of uric acid would doubtless also give rise to much the same effects, but the rapidity with which the effects followed mere faecal retention showed that the source of the symptoms must be referred to the intestines. It was very important also to bear in mind what Dr. Lauder Brunton had shown—viz., that a great amount of toxic matter might be produced from disorder of the stomach, as in various gastric catarrhs. Dr. Andriezen mentioned certain cases of hysteria with dilated stomach, in which washing out the stomach and giving small doses of naphthalin (five grains) had brought about a very prompt recovery. Of course, other cases of hysteria, those with a different pathogenesis, did not react to this kind of treatment. In the cases of hypochondriacal melancholia without neurotic taint or history he could bear out what the President had stated, and he believed that these belonged to much the same category as the hysteria noted above, only the changes were more extensive and severe, and the mental symptoms correspondingly increased. Toxic absorption from the gastro-intestinal tract, with or without morbid changes in the portal blood, could produce

chloroses and anæmias of various degrees, and in some cases of pernicious anæmia such poisons (different diamines) had been found in the faeces by Hunter. The sluggish movements in the gastro-intestinal tract and its lowered vitality in melancholia favored the development of ptomaine-producing micro-organisms. Such cases showed an increase of the aromatic sulphates in the urine—a good index of the amount of intestinal putrefaction going on. In epilepsy and in general paralysis the accumulation of such toxins in the blood favored and brought on convulsive attacks. The tendency of chronic Bright's disease to intensify existing symptoms of toxæmia and even to favor acute convulsions (*i. e.*, poisoning of the cerebral centres), as in pregnant women, was pointed out, and the importance of it in the clinical course of certain insanities emphasized. He was unable to agree entirely with Dr. Hamilton, that nearly all the rapidly developing manias and insanities, with hallucinations or acute mental confusion, were of auto-toxic origin. In many such cases quite other and adequate causes could be easily ascertained; though errors of diet and digestion, neglect of the bowels, and consequent auto-intoxication from the intestines, might play a minor part. He was chiefly impressed with the frequency with which such autotoxis might occur, and thus aggravate the symptoms in *already established* insanities, such as general paralytic, epileptic, alcoholic, and slowly developing delusional insanity. The clinical phenomena in these cases were a slight subacute delirium with restlessness, the patient stumbling and fumbling about in his room, with insomnia, which did not react to the usual sedatives and hypnotics, and where the temperature was slightly raised, the tongue furred, the breath offensive, and the skin and flesh peculiarly liable to undue markings like bruising, even from mere restlessness and the pressure of garments alone. Where he had examined the urines in such cases (about nine or ten cases) he had noticed considerable excess of indican, as compared with the same case after such a delirious episode in the course of the insanity was over. Such cases reacted well to brisk purgation and enemata with a predominantly farinaceous and milk diet: calomel was excellent for the former, and it could with advantage be administered with a capsule of naphthol. Personally he had great faith also in capsules containing pure carbolic acid, given between meals if gastric fermentation co-existed. He referred to an important class—what he would call a diathetic class—of the insanities which the text-books as yet had not recognized. He did not refer to the so-called gouty or rheumatismal insanities, but to those associated with and growing in the soil of myxœdema and acromegaly, with a very constant and distinct physiognomy of their own, and with a pathogenesis that could be harmonized and well explained by the morbid changes present, changes which lay at the root of the mental as well as the bodily conditions. In the one case (myxœdema), a morbid process starting from the thyroid gland affected the whole capacity of the blood in regard to its power of taking up oxygen from the air. On examining the blood with the mercurial pump it was found that its gases O and CO<sub>2</sub> were much diminished, and by placing the individual in the apparatus for examining the gases of respiration, it was found out that he took in but little oxygen and correspondingly gave out but little CO<sub>2</sub> during life. Thus he suffered from weakness and dullness, from subnormal temperature, and from a tendency to the accumulation of incompletely oxidized bodies (fat, etc.) in his

tissues. Similarly in the insanity of acromegaly pituitary feeding gave corresponding benefit, and for those who cared to follow the function of this gland and its special relation to the brain and nervous system he would refer to his paper on the pituitary, published in the *British Medical Journal*, January, 1894. Finally, as to toxins formed in the central nervous organs, this possibility must not be overlooked. Toxines may form in muscle and gland from the chemical products generated during the activity of such tissues—*e. g.*, CO<sub>2</sub>, lactic acid, creatine, etc. Now, in the central nervous system there was a very complex lymph apparatus for the absorption, carrying off, and elimination of these metabolic waste products. The whole nervous tissue of brain and spinal cord and the sheaths of the cranial and spinal nerves were perforated by a system of lymph channels, which in the brain cortex itself formed a special prolongation around each of the larger nerve cells (pericellular lymph sacs), and which had peculiar relationships with the adventitial sheaths of the pia-arachnoid and intracerebral blood-vessels. In the general paralytic and in the chronic alcoholic these lymphatic structures were affected in a special and peculiar way, producing in places blockages of the lymph streams and overgrowth of these lymphatic (lymph-secreting and lymph-absorbing) cells, which, according to their local incidence and preponderance, affected different spots, centres, and tracts of the central nervous system. An associated paresis of the muscular coats of the blood-vessels followed by fusiform and ampullary dilatations of the vascular and lymphatic channels also coexisted and added to the complexity of the morbid involvement, and this apart from changes which took place in the dynamic connections of nerve cells (dynamic changes) and in the internal nutrition of the cells, bodies and protoplasm (nutritive changes). The products of metabolism of the nerve cells would thus be in places retained in the dilated or obstructed sacs and lymphatic channels, producing from time to time—*i. e.*, continuously or cumulatively—various symptoms of toxins; the toxine being in such cases the unescaped, uneliminated products of cell activity. He concluded by stating that more often than not toxic agencies played a part in the *course of an insanity which was already established*; in a small number they played a *truly causal* part, but that in any case they should be vigorously treated when indications of their presence existed, the treatment being lavage or enemata, purgation with calomel, and antiseptic drugs taken internally; while to aid the convalescent stage and its associated anæmia iron, extract of bone marrow, etc., were indicated.

Dr. HARE said that, in listening to the paper, he had been struck by the fact of the large amount of knowledge the ancients possessed on the subject-matter discussed by the author. The central point insisted upon was that of self-poisoning in relation to mental conditions; in other words, the connection between such states of the mind and of the nervous system and the processes of disintegration and disease within the body. But the physicians of two thousand years ago were well acquainted with these facts, and they used such terms as "melancholia" and "hypocondriasis," "black bile," and "under the cartilages," showing that the Greeks well knew the relation between mental disturbances and affections of the liver. But the physicians of the present day had demonstrated what was previously only known as the result of clinical observation. There was nothing of which he was more sure than this self-poison-

ing, not only in insanity, but in many other conditions; and doubtless they would sadly neglect the treatment of many cases of insanity if they did not pay attention to the condition of the digestive organs. He was glad to hear the author insist upon the value of calomel and purgatives.

Dr. THEODORE WILLIAMS observed that in this country one ought not to suffer so much from mental and other diseases due to defective excretion, because great attention was usually paid to regularity of bowels and the proper function of the skin. On this ground, if the author's hypotheses were correct, such mental disturbances ought to be much more common in countries where it was quite common for persons to have an action of the bowels only once a week, and then only from purgation, and it was well known that the skin was not so well looked after there as here.

Dr. BOWER suggested that probably the intestinal trouble was more often the result of the nervous trouble than the cause. In respect of alcoholic insanity, it was said that the neuroses made the patient drink, and the drink reacted on the neuroses. He thought that washing out the stomach and intestines was of the greatest possible advantage.

Dr. FORBES WINSLOW observed that the subject was a very difficult one unless one had practical experience in a large institution. Patients in private practice did not afford sufficient opportunities to justify them in coming to any conclusion on the subject. As, however, the question was being raised in the House of Commons as to the increase in the prevalence of insanity and its causes, it was a great thing to have a paper like the one to which they had just listened. The mention of the influence of uric acid in the system reminded him of a case of a man suffering from gout who had melancholia with monomania. After a time the presence of a stone in the bladder was made out, and on its removal all his delusions disappeared.

Dr. HAMILTON, in replying, thanked the president for his kind words of welcome and wished to say that his paper was simply suggestive of the vast possibilities of the subject. He had recognized the conditions so clearly enumerated by Sir Crichton Browne, which all played an important part in the causation of mental disease, and he proposed at a future time to publish further details of his investigations. The speaker was disposed to regard the conclusion of Dr. Haig, whose views of gout are so well known, as extreme in the present instance, and while he recognized the fact that increased uric-acid excretion was found in many nervous disorders, he regarded these phenomena as the result of intestinal derangement such as he, the speaker, had demonstrated, rather than the initial cause, and he referred to Dr. Haig's own writings in regard to the transferral of cerebral and joint symptoms as an illustration. While he recognized the importance of the study of insanities associated with myxedema and acromegaly, and the formation of certain alkaloids in the nervous system, he did not feel that the scope of the paper permitted him to go into this question, which seemed to have been so diligently studied by Dr. Andriezen. As to the query of his friend, Dr. Theodore Williams, regarding the antipathy of the French to water and to the carelessness regarding the ordinary functions of Nature and their relation with Gallie insanity as compared with the better habits of their Anglo-Saxon neighbors, he had his own views. In conclusion, while disclaiming any dogmatism, he still would insist that in most cases of suddenly developing

acute mania, and especially such forms as the puerperal and periodic varieties, the existence of intestinal auto-toxis could be very often found.

#### MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

*Twenty-second Annual Meeting, held in St. Paul on Tuesday, Wednesday, Thursday, and Friday, September 15, 16, 17, and 18, 1896.*

The President, Dr. HENRY O. WALKER, of Detroit, in the Chair.

(Continued from page 464.)

**Reinfection in Consumption.**—Dr. JOSEPH MUIR, of New York, said that statistics showed that a first attack was not usually fatal, and death was often found to be due to other causes. Primary infection was not usually due to inherited tendencies, but external conditions played a most important part. Consumption was best treated among the rich; frequently, indeed, a permanent cure was effected in this class of patients, so for evident reasons those who were poor should be given special attention. Patients who had been cured must not be allowed to return to their former environment. Redevelopment was inconsistent with clinical experience. Change of air and outdoor exercise and labor hardened and refreshed the tissues, and the respiratory impurities of former environment were no longer present. Reinfection might be prevented by thorough disinfection of the patient and his surroundings and by destruction of the sputum. This protected the patient against himself.

Dr. H. J. O'BRIEN, of St. Paul, was satisfied that there were many cases of reinfection. He stated that he had sent patients away, and in six months they would come back to die; by staying away they would sometimes escape contagion and reinfection.

Dr. J. A. LARRABEE, of Louisville, said that he had long believed that if a consumptive could have these conveniences and this care in the beginning, along with a forced feeding, in many cases we could check or entirely abort the disease. The most terrible mistake was made in sending subjects away for treatment. Home was best, no matter where that home was. Improve it as much as possible, but leave the patients among friends. He thought there was much in the idea of reinfection.

Dr. R. H. BABCOCK, of Chicago, emphasized in the strongest possible terms the idea that, if patients were sent away and they improved, they must stay away permanently.

**The Indications for and Demonstrations of Removal of the Gasserian Ganglion.**—Dr. J. B. MURPHY, of Chicago, demonstrated the technics of the operation on a cadaver head. The operation might seem heroic, but heroic measures were necessary in a condition so severe as trigeminal or facial neuralgia. Patients would submit to anything in the hope of relief. This method of operating was simpler and resulted in less deformity, as well as being more certain in its results, than any other yet suggested. Dr. Murphy had always suggested some conditional treatment, especially that with castor oil, before resorting to so heroic and serious a measure as this operation. The trouble, however, with all such treatments was that they did not give a permanent relief. The castor-oil treatment had given temporary relief in several cases.

Dr. A. J. OCHSNER, of Chicago, thought that the author had given a most beautiful demonstration of a difficult operation, one which, in his hands, no doubt would give a large measure of success. He himself hesitated to operate in these cases of facial neuralgia, for the very fact that they were necessarily of a serious nature. He had recently had some experience in these cases in the use of castor oil. He had given this remedy in half-ounce doses twice daily for ten days or two weeks at a time, and to his surprise it had thus far proved a most excellent remedy. As to whether the results would be permanent he could not say, but no case had yet returned to its former severity. He advised repeating the castor oil whenever there were indications of a returning attack.

#### Electro-diagnosis and Electro-therapeutics Simplified.

—Dr. HUGH T. PATRICK, of Chicago, read a paper on this subject, in which he stated that electro-diagnosis was limited to the affirmation or denial of a lesion of the lower neuron; meaning one of the motor cells in the spinal cord, or of the nerve fibre, the peripheral nerves springing from those cells. A lesion of this neuron caused the reaction of degeneration, and this, stripped of all unnecessary technicalities, might be recognized by two variations from the normal—namely, a loss or very considerable diminution of faradaic contractions, and the slow, wormlike contraction of the muscles to interruption of the galvanic current.

In the electro-therapeutics of organic disease of the nervous system, applications of electricity through the brain might be entirely discarded as useless. Electricity through the spinal cord was little better. In diseases of the peripheral nerves it probably hastened recovery, and that current was to be chosen which the better caused muscular contraction.

In functional nervous disease electricity was of more practical value than in organic affections, but it was almost impossible to determine what proportion of this good effect was due to mental impression—to suggestion.

The galvanic current was chosen for facial neuralgia, costal neuralgia, and sciatica; the faradaic for lumbago, hysterical anesthesia, paralysis, and pain; the galvanic for exophthalmic goitre and sometimes for neurasthenic headache and backache. For facial spasms, tic, spasmodic torticollis, tremor, and chorea, electricity is useful aside from the mental effect.

**A New Method of Fastening the Round Ligaments in Alexander's Operation, with Little Disturbance of their Anatomical Relations.**—Dr. J. FRANK, of Chicago, stated, in a paper on this subject, that an incision an inch long was made midway between the anterior superior spine of the ilium and the spine of the pubes, a trifle above Poupart's ligament. The transversalis muscle was pushed back and the ligament lifted out with a blunt hook. It was drawn out until the uterus was in the correct position. No great difference was experienced if the peritoneal cavity should be opened. Usually three sutures were required to close the wound; the first one being taken as low as possible through one flap of the peritoneum, then through the round ligament itself. Instead of drawing the ligament through the fascia, as formerly practised, it was replaced in its anatomical position, beneath the transversalis muscle. By this method sloughing of the ligament was prevented. This operation was the simplest of all yet proposed for the purpose. As a suture material, kangaroo tendon had proved most satisfactory in the speaker's

experience. A pessary should be fitted before the operation, and afterward worn as long as might be deemed necessary by the surgeon.

Dr. A. J. OCHSNER, of Chicago, considered this method a great improvement in the operation, because it did away with tearing and injuring the tissues. This method left the organ in the best possible condition for recovery, with sufficient adhesions to protect the ligament from being drawn out again, yet without unnecessary adhesions. He had examined some of the author's cases and confirmed his favorable report.

**Amygdalotomy by Cautery Dissection.**—Dr. J. HOMER COULTER, of Chicago, said that no subject in surgery or medicine had been much more prolific in interest and discussion than that of the tonsil. In the past ten years over six hundred papers have been written on that subject alone. The size of the normal tonsil was still a subject of discussion with throat specialists. Some alleged that there was normally no tonsil to be seen; however, the most usual opinion was that there existed normally a collection of follicles between the pillars of the fauces protruding slightly above them. The tonsil was an almond-shaped gland, larger at one end than at the other, and somewhat flattened.

The methods usually employed for its ablation were the use of the guillotine, that of ignipuncture, that of the cold or cautery snare, and that of the knife. Each of these methods had practical objections to its use. The most important of these objections, and one which applied to all of them, was the fact that by no one of them could the entire gland be taken out. Unless this was done the part remaining would oftentimes produce as much trouble as the former condition did. Dr. Coulter proposed the following operation, which, he said, obviated this objection entirely if properly performed:

With a well-heated small galvano-cautery the pillars were dissected away from the tonsil to half of its extent. The gland was then, with a suitable forceps, drawn well out and thoroughly and entirely dissected out to about half of its extent. This portion was then cut off and the surface treated with a strong solution of silver nitrate. In a week or ten days the other portion of the tonsil was removed in the same manner. This operation would give cosmetic as well as practical results unobtainable by any other process yet suggested.

Dr. H. W. LOEB, of St. Louis, stated that he had been very much interested in the presentation of this new method of amygdalotomy. He believed most decidedly in what the author had said about the lack of skill of many who attempted to remove the tonsils by the ordinary method. Very often they would take a piece off and by showing it make the patient or his friends imagine they had performed amygdalotomy. If, said Dr. Loeb, the operator could see that patient five or six years later suffering from the same affections, to which the remainder of the tonsil became a subject, he would not be so well pleased. Removing a part could only improve the symptoms then present, and it did not signify that the tonsil would remain quiescent. It was unfortunate that so valuable a method was not applicable to young children; for adults it could not be improved upon. The speaker had been practising this method with some modifications for some years. Instead of performing so much dissection, it had been his plan to remove as much of the tissue as he could get in an electric snare. This was repeated as often as might be necessary to remove all the glandular substance. He thought the method caused less

soreness and less pain than Dr. Coulter's, and in many cases, particularly in children, the results would be just as satisfactory. Furthermore, his own method was applicable in case of young children.

This method of dissection, he said, was one that must commend itself in a great number of cases as being the very best possible. He most heartily agreed with the author that removal of the whole tonsil was an absolute requisite if the patient was to be cured. As to the voice changes suggested by some, he believed ablation of the tonsil did have a decided effect on the voice register, but he also believed it was always in the way of improvement. He stated his disbelief in the uric-acid diathesis having anything to do with amygdalitis, further than as a concomitant condition. The speaker stated that he had had the opportunity of seeing some of these cases, and that he had never seen the cosmetic results equaled.

**The Surgical Treatment of Pyloric Obstruction.**—This was the title of a paper read by Dr. W. J. MAYO, of Rochester, Minnesota. This subject, he thought, had not received the attention it demanded from American surgeons. The diagnosis of serious pyloric disease was often a matter of the greatest difficulty. He had found that the free use of strychnine for several days previous to the operation was of great value in preventing shock. The stomach should always be thoroughly washed out a few hours before the operation and nothing eaten afterward. For combating the shock, besides strychnine and dry heat, a rectal enema of a pint of hot coffee should be given. Nourishment by the stomach should not be too long withheld afterward. For twenty-four hours rectal alimentation should be used; in thirty-six hours some champagne; later, buttermilk and a gradually increasing diet.

Dr. A. F. HOUSE, of Cleveland, was opposed to the use of the Murphy button and did not consider it the ideal method, as his experience had been somewhat unsatisfactory. He believed the less foreign matter that got into the wound when the bowel was united to the stomach, the better the result. He had discarded the button for the suture method. He believed much of the success in the use of the button depended on skill in using it.

Dr. F. F. LAWRENCE, of Columbus, thought that in cases of malignant disease we could not promise more than temporary relief and perhaps prolongation of life for a brief period. The simpler the operation the better for the patient. He doubted very much if resection in cases of malignancy would give a permanent cure.

Dr. A. J. OCHSNER said that regarding the hydrochloric-acid test, he was convinced it was a most treacherous test. If we suspected carcinoma the best thing to do was to perform colostomy. In some twenty cases he had used irrigation of the stomach with decided satisfaction. In this way the patient would sometimes become well enough nourished to better stand an operation when it was desirable.

**Conditions which may simulate Organic Obstruction of the Rectum.**—Dr. THOMAS H. MANLEY, of New York, read a paper on this subject (see page 436).

Dr. I. N. LOVE, of St. Louis, said there could be no question that a majority of the diseases which afflicted human beings, male or female, were largely dependent upon constipation, and consequently upon obstruction of the rectum. Physicians were all of the opinion that a large part of the diseases of women were due to that factor. Their habits of life, their social, domestic, and

maternal duties, seriously interfered with that regularity which was so essential. The pelvis of a woman should be left to be occupied by the proper pelvic organs. A fecal accumulation was a mechanical obstruction pressing these organs out of position. He was thoroughly in sympathy with the position taken by Dr. Manley, and he thought physicians should impress the mothers and young ladies in their homes that it was not only unsafe, but unæsthetic and inartistic to retain these accumulations that should have a place in the sewers of the city. They should be made to realize that the alimentary canal was a food track in its entirety, and that waste material should be removed from the bowels. There should be no necessity for cathartics or purgatives. Happy living, right living, successful living, depended quite as much on proper elimination as on anything else.

**Submucous Linear Cauterization; a New Method for Reduction of Hypertrophies of the Conchæ.**—Dr. NORVAL H. PIERCE, of Chicago, called attention to the various methods ordinarily used for the reduction of such hypertrophies, and showed the disadvantages of each. The distinction between hypertrophy and turgescence was pointed out. The operation proposed by the author was as follows: A small incision was made in the hypertrophied membrane, then with a blunt flat probe the mucous membrane was carefully separated from the erectile tissue underneath. Then a sound, the end of which was cup-shaped, and upon which had been fused a few crystals of chromic acid, was inserted in the incision, and the track already made by the probe was thus cauterized. The advantages of this method were that there was no hæmorrhage, it was less painful than any other, and the functional activity of the mucous membrane was not in the least impaired. Patients would submit to this operation more willingly than to the burning of the cautery. The method was the simplest of any yet suggested. The reaction was usually insignificant. There was no slough. The danger of atresia was obviated.

Dr. COULTER complimented the author on the originality of his method and its various points of excellence, which were, at least theoretically, present. The main object to be attained was not only the reduction of hypertrophy, but the retention of functional activity as well. Many operators in using the cautery destroyed too much of the mucous membrane and did not go deep enough to remove or destroy any substantial amount of the tissue underneath, which in reality was the seat of the disease. He suggested the possibility of the chromic acid being left within the operative field, in which case an undesirable slough would necessarily follow.

The practice of many rhinologists of using a broad flat electrode and destroying a large amount of the mucous membrane, and not going down to the bone, was to be deplored as irrational, unscientific, and impracticable, inasmuch as by such measures they did not cure the hypertrophy, but did very materially reduce the functional capacity of the nasal mucous membrane.

Dr. W. L. BALLENGER, of Chicago, thought that the rationale of Dr. Pierce's operation was certainly an ideal one. If the hypertrophy could be removed without the destruction of any mucous membrane, little more was to be desired.

Dr. H. W. LOEB, of St. Louis, said that the operation seemed to him to be a thoroughly scientific one, if the

mucous membrane and its function could thus be preserved. He thought that antiseptis and asepis would both be necessities with this method. He asked why we could not use a platinum wire properly made and introduced in the same manner. He had seen blindness result from cauterization of the inferior turbinates, and questioned whether there was not danger in the use of the chromic acid by this method.

Dr. STUCKEY said we must determine whether it was an hypertrophy or simply a turgescence. If the latter, it might be simply an acute condition caused by some idiosyncrasy. If it was a true hypertrophy, this method would seem to be an excellent one, although it required a considerable amount of technical skill. He was becoming more and more skeptical as to the use of cocaine in the nose. There was the greatest danger of producing the cocaine habit by its use. He was able to get the same results without danger and with less systemic disturbance by the use of a harmless solution of acetanilide.

Dr. MUIR, of New York, stated, in reference to Dr. Loeb's question, that in New York the submucous cauterization with the cautery wire had been tried, but in each and every case an undesirable slough had been produced.

Dr. LOVE thought chromic acid needed to be used very carefully. It was very penetrating and must be controlled, but when controlled it was one of the kindest cauteries there were. It produced an eschar that clung close to the bone. The idea of the author that the nutrition of the hypertrophy must be cut off was a most scientific and practical one. He protested against the indiscriminate and careless use of cocaine in the nose. There were going about the country to-day hundreds of men and women who were miserable victims of the medical profession's careless use of cocaine.

(To be continued.)

## New Inventions, etc.

### A SHADE FOR THE WELSBACH LIGHT.

By WALTER F. CHAPPELL, M. D.

THE superiority of the Welsbach light for illumination of the upper air tract will be conceded by all who have used it. Without some shade the glare and brilliancy of this light are, however, somewhat unpleasant. As a condenser is unnecessary, the accompanying illustration presents a shade which the writer has used for some time, and he finds that it meets all the requirements at a minimum cost. It consists of a section of iron or aluminum tubing, nickel-plated on both sides and of sufficient diameter to fit over an ordinary (one-piece) mica chimney or standard. A rim is turned up on the lower end of the shade and rests on the supports which carry the chimney. The opening in the shade corresponds in size

and shape to the mantle of the Welsbach light, and admits of direct steady light without any side glare or reflections.

## Miscellany.

### The Action of *Viburnum Prunifolium* (Black Haw).

--In the November number of the *Edinburgh Medical Journal* Dr. Theodore Shennan remarks that the literature of *Viburnum prunifolium* is almost wholly clinical, and that it is difficult to draw conclusions as to its physiological action.

Dr. Phares, of Newtonia, Mississippi, he says, has the credit of initiating its use. His paper, published in 1866, recommended it as astringent, diuretic, tonic, and antispasmodic, but chiefly as a remedy for dysmenorrhœa and as a preventive of abortion.

Little more is heard of it until 1876, when Dr. Jenks, of Detroit, revived its use. He employed it in menorrhagia, metrorrhagia, and dysmenorrhœa with menorrhagia. He attributed a great deal of its value to the presence of a body similar to valerician acid.

Rockwell, in 1879, used it in dysmenorrhœa. He considered it was indicated in delicate, nervous women in whom pain was due to slight ante flexion, slight endotrachelitis, or partial stenosis, or where it was neuralgic in character. He classed it as anodyne, antispasmodic and tonic. The last term is very indefinite, Dr. Shennan thinks, though in one of his cases he noticed a relief of nausea or sickness which followed the administration of viburnum.

Abbot, in 1879, used it in dysmenorrhœa with great success, as also Curtis (1879) and Lyman.

Chadwick, in 1879, found it gave relief in many cases, but success was not invariable, or so brilliant as previous papers had led him to expect. Its action was similar but not superior to that of zinc valerianate.

Dr. R. L. Payne read a paper on *Viburnum prunifolium* before the Medical Society of North Carolina in 1888. This is one of the few papers which treat the subject scientifically, and describe experiments carried out on the lower animals. He refers to the literature of viburnum, and the want of definite rules for its use. He experimented with the ordinary alcoholic liquid extract; or with the solid extract rubbed up with water, with the view of getting rid of the vitiating effects of the alcohol contained in the fluid extract. He found that both had a similar effect. His results were as follows: Paralysis and loss of reflex motion, both with mechanical and with chemical stimuli. He got reactions with electrical stimuli—whether faradaic or galvanic is not stated—one pole to the spine, the other to the limb. He gave as much as half an ounce of the fluid extract to rabbits, and the amount of alcohol contained must undoubtedly have had an effect on the tracing. The author thinks that his experiments on rabbits prove this. In rabbits (the solid extract being used, rubbed up with water), the blood pressure was found to fall very rapidly after the injection of a syringe of the fluid into the jugular vein. Here, Dr. Shennan thinks, evidently no care had been taken to make the fluid neutral or slightly alkaline, and the resins, which are present in considerable quantity, were not removed before injection. Dr. Payne's tracings show a marked effect on the blood pressure, but at parts suggest, by the weakness of the heart curves, that there may have been some clotting in the cannula. There was evidently no balancing of pressure in the vessels by use of a column of mercury, and, as the blood was thus allowed to pass

for some distance into the tube leading to the recording apparatus, the tendency was for it to clot. The author states that he has found this clotting to be very troublesome in his own experiments.

Dr. Payne concluded that there was no effect on sensibility. The chief action was on motion, paralysis, loss of voluntary motion, loss of reflex power, the extent being governed entirely by the amount of the drug used. The pupils contracted in cold-blooded animals and did not change in warm-blooded animals. Muscular irritability was lost after lethal doses, but nerve conduction was lost before muscular contractility. Probably the action was chiefly on the spinal cord and its posterior columns. The heart was quick and feeble in its action, and the blood pressure lowered; in lethal doses the heart stopped before respiration.

Dr. Payne, continues the author, recommended its use in diseases with increased excitability of the motor centres—hysteria, in hystero-epilepsy, in *petit mal*; in paralysis agitans, and in the dysmenorrhœa sometimes designated as ovarian or spasmodic. He asserted that it was harmful in menorrhagia due to congestion of the portal circulation, subinvolution of the uterus, metritis, erosions of the cervix, and fibroid tumors. It was preventive of abortion and very useful in habitual abortion. It had a paralyzant action on the uterus.

Dr. J. Hinton, of Detroit, in 1889, applied it for the control of false pains, and even of labor pains. He has never observed post-partum hæmorrhage or severe after-pains when using this drug.

Parker used it for the irregularities of menstruation.

Joseph, of Landeck, in Schlesien, has an important paper on the subject. He recommends viburnum very strongly in virginal dysmenorrhœa. He used it in two cases of habitual abortion, in which he was unsuccessful; but he does not consider this a sufficient trial. Of the forms of dysmenorrhœa, that is most relieved which is brought about by mechanical obstruction—for example, congenital or acquired ante flexion, as opposed to congestive dysmenorrhœa, which is more common in married women. The amount of the flux was diminished, and sank to normal; moreover, the remedy changed the interrupted course to one more continuous. He recommends it as an antispasmodic, and not only in uterine or intestinal colic, but also in other conditions of cramp, such as of voluntary muscles.

Dr. Boal prefers viburnum to opium in many cases, as it is more easily borne and is readily retained by the stomach. It is very beneficial in spasmodic dysmenorrhœa, and gives relief when dysmenorrhœa is due to flexion or to stenosis. It relieves pain preceding and during menstruation. Even if this one action was proved, says the author, and it was able to take the place of opium or alcohol, viburnum would be very serviceable.

Blackerby used it in habitual abortion, and cites a very conclusive case. A patient of his had had six abortions. Viburnum was administered during the seventh pregnancy, which went to term and ended in the birth of a living child. The eighth pregnancy had a similar result under the same treatment.

Many other cases, says Dr. Shennan, have been related in which relief was obtained in threatening abortion after overexertion.

In regard to the indications for the use of this drug, they are as follows: 1. In *habitual abortion*, where this is not caused by syphilitic infection or by fatty placenta, good results undoubtedly seem to follow its

use. 2. In *threatening abortion*, however caused, and at any period of gestation, if the patient is treated soon enough, it seems to be very successful. 3. In *dysmenorrhœa*, if functional, spasmodic, or ovarian, or attended with menorrhagia, it often cures. If there is flexion or stenosis, it gives great relief, though, of course, it can not cure. 4. In the menorrhagias and metrorrhagia of the menopause and in the nervous disorders of that time it is very beneficial. 5. *After-pains* are so readily relieved by it that some, like Auvard, consider that its use is dangerous unless all clots are cleared out of the uterus previously. 6. It may be used in the diagnosis of *false pains*, as it speedily relieves them. 7. It is also used with success in *colicky diarrhœa* and in *dysentery*. Some even maintain that it has a curative effect on cramps of voluntary muscles.

Concerning the physiological effects on animals and man, Dr. Shennan has undertaken some experiments, from the results of which he draws the following conclusions: In mammals, warm-blooded animals, owing to the difficulty of giving a large enough dose hypodermically, there is no marked effect, except drowsiness and some lessening of motor power. If the substance is introduced into the heart directly, there is rapid lowering of blood pressure to about half the normal, with slow return to near the normal as the drug is eliminated.

Although too much reliance must not be placed on experimental results in cold-blooded animals as applicable to warm-blooded animals, including man, we may be allowed, says the author, to take something from these results and use them as probably applicable.

Thus, there are probably some diminution of reflex irritability, a quieting effect on involuntary muscle, and possibly some lowering of blood pressure, which, even though small, might afford relief in congested conditions. Then, and very important, there is the effect of the valerician or viburnic acid in neurotic and hysterical conditions.

In the *Pharmacopœia* there are many drugs capable of bringing about all these desired effects. Why, then, he asks, use *Viburnum prunifolium*? Opium is one of our sheet-anchors, but then there are dangers and inconveniences attending its use. The patient may acquire the opium habit, the constipation caused by it is very troublesome, and it is very toxic.

Viburnum has similar good effects, though not so strong. It is a good form in which to administer valerician acid. Its effect upon unstriated muscle, though not so strong as that of opium, gives the relief necessary. It has scarcely any effect in causing constipation.

Toxic effects have been noticed only with very considerable doses. Herrick has seen disturbance of vision, dryness of the mouth, and headaches; and Wilson has observed similar conditions, but these were with doses larger than are usually administered to man.

**The American Electro-therapeutic Association.**—Dr. Max Einhorn, the secretary, announces that at the sixth annual meeting of this association the following officers were elected: President, Dr. William Thomas Bishop, of Harrisburg, Pennsylvania; vice-presidents, Dr. Emil Heuel, of New York, and Dr. F. B. Bishop, of Washington; treasurer, Dr. Richard J. Nunn, of Savannah; secretary, Dr. Max Einhorn, of New York; members of the executive council, Dr. William J. Herd-

man, of Ann Arbor, Michigan; Dr. G. Betton Massey, of Philadelphia; Dr. Robert Newman and Dr. Emil Heuel, of New York; and Dr. Schavoir, of Stamford, Connecticut. The following committees were appointed by the president for the ensuing year:

*On Induction Coils and Alternators.*—Mr. A. E. Kennelly, of Philadelphia; Dr. G. Betton Massey, of Philadelphia; and Dr. D. R. Brower, of Chicago.

*On Meters.*—Dr. Caleb Brown, of Sac City, Iowa, and Dr. M. A. Cleaves and Mr. Edwin W. Hammer, of New York.

*On Motors, Constant Current Generators, and Controllers.*—Dr. William J. Herdman, of Ann Arbor, Michigan; Dr. Robert Newman, of New York; and Mr. G. R. Brown, of Brooklyn.

*On Static Machines and Condensers.*—Dr. William J. Morton, of New York; Dr. W. H. White, of Boston; and Dr. William J. Herdman, of Ann Arbor, Michigan.

*On Electrodes.*—Dr. Charles R. Dickson, of Toronto, Ontario; Dr. Lucy Hall-Brown, of Brooklyn; and Dr. John Gerin, of Auburn, N. Y.

*On Electric-light Apparatus for Diagnosis and Therapy and the Röntgen X Ray.*—Mr. J. J. Carty, of New York; Dr. F. Schavoir, of Stamford, Connecticut; and Dr. Stephen Weeks, of Portland, Maine.

The next annual meeting will be held in Harrisburg, Pennsylvania, on Tuesday, Wednesday, and Thursday, September 21, 22, and 23, 1897.

**The Treatment of Delirium Tremens with Chloride of Ammonium.**—Dr. Gilbert G. Cottam, in the November number of *Medicine*, says it is an almost universal experience that the accepted routine treatment of delirium tremens is unsatisfactory when applied at the bedside. In part this is due to the effect of alcohol itself, and perhaps more largely to the fact that inebriates habitually indulge largely in morphine, chloral, bromide, etc. In this way a tolerance for sedatives and hypnotics is established which renders these agents quite inoperative when exhibited for the purpose of subduing the delirium.

He states that in 1893, during his hospital internship, he had abundant opportunity of demonstrating the truth of the foregoing proposition. While he was casting about for a substitute his attention was drawn to chloride of ammonium, which, in moderate doses, from ten to thirty grains, will, he says, effectually overcome ordinary alcoholic intoxication in a short time. Its properties, stimulant and eliminative, led him to believe that it could be used with good effect in larger doses in the more pronounced symptoms of alcoholism.

A suitable case in which to test the remedy did not present itself until last year, when the author was called late one night to see a laboring man who had been in the habit of drinking intermittently for the previous ten years. In 1891 he was treated according to the Keeley method, which "cure" was followed by a speedy relapse. Three days before coming under the author's observation he began drinking heavily, which culminated in an attack of acute delirium for which Dr. Cottam was consulted. The patient was found in bed, dressed, and had the usual reptile hallucinations. The pulse was somewhat rapid, full, and strong, and quite typical of alcoholism. He was very restless, moving incessantly, at times starting from bed and making efforts to ascend the sides of the room. He would frequently have fallen had he not been restrained. The

history and symptoms were those of a typical case of delirium tremens.

Having some knowledge of the patient and his tolerance of drugs, Dr. Cottam began by administering a grain of morphine hypodermically. This was without the slightest effect. Several hours after the administration of the morphine, and after the symptoms had all become aggravated, he was given a drachm of chloride of ammonium. This was promptly vomited. After a short time another was given, which was retained. It acted quickly and favorably. In fifteen minutes the hallucinations of snakes and lizards had disappeared, and he had become quite rational. In forty minutes he was asleep, and it was not thought necessary to continue the administration of the drug.

It was afterward ascertained that this was the patient's third attack. He had used morphine often and in large doses for the relief of headache and insomnia following overindulgence in alcohol.

This case, says the author, may, of course, have been exceptional in the favorable action exercised by the ammonium salt on the alcoholic delirium. It is improper, he adds, to draw conclusions from a single case, but he offers these notes with the hope that they will encourage those in a position to do so to try the drug in large doses in the treatment of this troublesome affection.

**The Psychic Influence of the Night Season.**—Dr. A. B. Richardson, of the Columbus State Hospital, Ohio, contributes an interesting article on this subject to the October number of the *American Journal of Insanity*, of which the following is the substance:

The diurnal alternation of night and day is not without interest in its psychological influence upon the human race. The ebb and flow of energy that it represents is an element of vast importance in our existence. Day is the period of active energizing, night that of repose and recuperation. In the former there is a state of elevation, a natural confidence and a willingness to undertake whatever responsibility may present itself. In the latter there is just as truly a natural depression, a timidity and cowardice in confronting the obstacles in our path.

The accumulated inheritances of countless ages through this ever-recurring elevation and depression have stamped this wavelike characteristic upon every mental operation. The ebb and flow in mind activities is universal. It permeates every form of psychic energy. It gives coloring to our emotional states. It is seldom that in any individual, or at any time, we find an accurate ideal equipoise. We are either in a state of exaltation or of depression, either too confident and self-reliant, with vision too highly colored and enthusiasm too much exalted to be justified by the circumstances of our environment, or we are in the opposite condition of depression and timid cowardice, with little confidence in our powers and an undue extravagance in our estimate of the difficulties in our pathway. Even when this becomes impersonal and is crystallized into the energy of nations the same tendency is seen. One extreme of opinion almost invariably follows another. The pendulum of thought and psychic energy forever swings first to one extreme of its movement, then to the other. The world is apparently unable to calmly and deliberately maintain a correct status in opinion or practice. It is either too credulous or too suspicious, too indulgent or too intolerant, too confident in

its knowledge or too ready to find cause for criticism and disbelief. How far this oscillation between antipodal points depends upon or is influenced by the diurnal withdrawal and return of the solar influence, says Dr. Richardson, is possessed of more than merely curious interest. It is not unworthy of a few moments' time and study.

Night is the withdrawal of the light and heat of the sun. No amount and no intensity of artificial illumination will replace this withdrawal. In spite of all the artifice and invention of man, night still reigns supreme. No matter how much we may attempt it we can not turn night into day. Although we may supply light and noise and the stir and bustle of day, it is still night. The tendency toward repose and a letting down of the armored guard that the activity of day brings with it are still there.

There is an element of timidity and fear in our organization that is greatly enhanced at night, and this may largely account for our increased credulity at that time. Our belief is born of our fears. How many physicians are there, he asks, who can not bring proof of this? Many of their night calls are due to the greater uneasiness of the patient, or his parents or friends, on the approach of night. They are affrighted then at symptoms that would not alarm them during the day, and hasten to send for the physician to relieve them of the fears that night itself has seemed to bring to them. Again, in many cases of illness there is an actual exacerbation in the symptoms with the approach of night. This is notably so in children. This may have a double origin. It may be due to the increased timidity of the individual at that time, and a consequent increase in the subjective sensations of the disease, and it may be due, at least in part, to the natural letting down of the power of resistance of the organism that we believe does occur during the night. Whatever may be the explanation, says Dr. Richardson, the fact is indisputable, and there is not a mother who does not dread the approach of night when her child is seized with a dangerous illness.

A still more interesting fact is the influence of the night season over moral attributes. There is a letting down in this direction which is very similar to that seen in the field of the emotions. The power of resistance to things evil is then diminished. The very mystery of night is conducive to an expanding of the imagination. There is a sharpening of all the senses that renders every sound clearer and makes every object stand out in greatly heightened distinctness. The sense of hearing is more acute, the eyesight detects objects more readily, the touch is quickened, and the whole being is more sensitive. Whether this is evidence of weakness, says the author, the hyperæsthesia of nervous exhaustion, or a quickening of every tissue in its instinctive strife for self-preservation, may be beyond us; of the fact we all have proof in the promptings of our own hearts.

The most dangerous hours of the twenty-four, he continues, to the melancholic are the latter hours of the night. The depression is then greatest, obstacles then seem most insurmountable, and the power of resistance to the suicidal impulse is then least effective. He has often found it necessary to give special instructions to attendants in this regard. This all goes to demonstrate, he says, that the energy of the patient is at its lowest ebb during the night; that there is then a natural depression and timidity.

What is experienced by the sane, influences also the insane, and obstacles and misfortunes then mount highest in their vision. There is doubtless scarcely a melancholic who does not at one time or another have suggestions of self-destruction, and whether or not they will control him depends entirely on the strength of the suggestion. The particular hour of the night is often sufficient to throw the balance against the poor unfortunate, and in this sense it becomes an actual exciting cause of suicide.

It is a fact that we should not lose sight of, and the author is convinced that it has its basis in a physiological variation of the organism at this hour. Just as certainly, says Dr. Richardson, as there is a physiological condition of exaltation and sense of well-being, so also is there a physiological state of depression and irritation with our environment. It is not necessary to assume that this implies disease. It does not. It is simply an inevitable reaction, such as is seen in all physiological phenomena. There is a coming and a going, a rise and fall, a season of joy and a sense of pain, and he is persuaded that the greatest factor that instituted and enforces this law of Nature is the daily cycle of the earth on its axis, with its necessary presentation and withdrawal of organic life to that source of all life and energy, the solar centre. In its presence we imbibe warmth, energy, confidence, life; in its absence we suffer the reaction of coldness, lowered ambition, lack of confidence, and moral cowardice—a curious physiological fact and one not without its practical application.

**The Spinal Cord of a Rabbit Successfully Used, as a Graft in the Median Nerve of a Man.**—In the *British Medical Journal* for October 31st Mr. Mayo Robson relates the following case, which, he thinks, will be found of interest: The patient, a gardener, was admitted into the Leeds Infirmary on January 18, 1890. He gave the history of having seven months before fallen on a scythe, which had produced a deep incision on the lower and inner part of the upper arm, the brachial artery having been divided. At the time of injury a surgeon was sent for; the artery was ligatured, and the two ends of a divided nerve were sutured. The wound healed slowly by granulation. On admission to the infirmary, the patient was in robust health. There was a scar on the inner aspect of the right arm, extending from a point two inches above and to the inner side of the olecranon process obliquely upward and forward for about three inches to the inner side of the prominence of the biceps. The circumference of the right forearm was two thirds of an inch less than that of the left, that of the wrist half an inch less. The hypothenar eminence was absent, the thenar eminence was much atrophied, and the interosseal muscles were very much wasted. He had entirely lost the power of grasping, though he could flex the metacarpophalangeal articulations to a right angle. Extension of the wrist was possible, apparently with considerable exertion, but flexion of the wrist was impossible against gravity. The thumb could not be adducted or the fingers separated or approximated. All the muscles acting on the wrist and hand which had their nerve supply from the median and ulnar nerves were paralyzed, while those supplied by the musculo-spiral were capable of acting.

Sensation was absent along a narrow line extending over the inner and anterior aspect of the ulnar border of the forearm from the elbow to the wrist. In the

palm sensation was absent except over the thenar eminence and part of the proximal phalanx of the thumb. On the back of the hand it was absent, internal to a line drawn backward from the cleft of the middle and ring fingers, also over the whole of the back of the little and ring fingers, as well as over the distal one and a half phalanges of the index and middle fingers.

On January 30, 1890, the limb having been previously aseptized, ether was administered, and an incision made along the line of the cicatrix, which was prolonged some distance upward and downward, and supplemented by a transverse incision about an inch above the elbow. The ulnar nerve was soon exposed above the internal condyle, firmly fixed in fibrous tissue. The lower end of the upper segment, which was bulbous, was connected by fibrous tissue with the upper end of the lower segment. A long search then took place for the median nerve, as the large cicatrix had altered the normal anatomy of the parts. A small nerve was discovered at the upper part of the wound, which proved to be the internal cutaneous. The lower end of this nerve was discovered later, and united to the upper by a catgut suture. The internal intermuscular septum was divided an inch and a half above the internal condyle, and the atrophied remains of the brachial artery were defined. At last, at about the middle of the upper arm, the bulbous lower end of the upper segment of the median nerve was discovered well under and concealed by the belly of the biceps. Then the upper end of the lower segment was found just above the bend of the elbow. This extremity was expanded and sent ramifications into the cicatrix. The fibrous tissue between the ends of the ulnar nerve was excised, and the two healthy portions were united by grafting strands of the sciatic nerve of a rabbit so as to fill up the gap and produce continuity. It was quite impossible to bring the divided ends of the median nerve nearer to each other than two inches and a half. All the nerve tissue having been exhausted in uniting the ulnar nerve, the spinal cord of a rabbit just killed was used as a graft to connect the ends of the median nerve, the inserted cord lying loose and quite free from tension when finally placed in position. Fine catgut sutures were used throughout. The edges of the wound were brought together and the usual dressings applied, the arm being fixed on a rectangular splint. Healing occurred by first intention, and there was entire absence of fever or pain.

On February 10th the patient could feel the scratch of a pin on the flexor aspect of the first phalanx of the thumb, as well as at the root of the index finger. He could tell when the hairs on the back of the first phalanges of the ring and little fingers were pulled, but could not feel the scratch of a pin in that position.

On February 17th sensation had returned over the whole of the palmar surface of the thumb and the proximate phalanx of the index finger.

On March 4th sensation seemed to be creeping slowly along the first finger, and to be present over the whole of the palmar area supplied by the median nerve, and extending as far down as the web of the fingers, and a short distance along the middle finger. As yet there was no marked improvement in the ulnar distribution.

On March 6th electrical reaction to faradism was absent in the muscles. C. C. 15 M. A. P.; C. C. C. equal to A. C. C. in flexors; C. C. C. greater than A. C. C. in extensors.

The muscles were gradually developing, and the general nutrition of the hand showed improvement.

There was a slight power of grasp and there was some power of flexion of the wrist, as well as slight power of adduction of the thumb and flexion of the fingers. Sensation was felt all over the thumb and index finger, in the second finger up to the first phalanx on the palmar aspect, also in the third finger, though less distinct. No sensation could be elicited over the distribution of the ulnar nerve.

On March 30th he began to have sharp shooting pains along the distribution of the ulnar nerve.

On April 1st the flexors of the forearm began to react visibly to C. C. C., though the muscles of the thenar eminence did not, and there was no faradaic reaction.

On April 30th sensation was returning at the back of the ring finger, and the flexors now reacted to A. C. C. of 5 M. A. P.

On June 13th the nutrition of the hand was much improved, and there was a greater feeling of warmth in it. The patient could pick up small objects, and, although the grasp was not powerful, it was much improved. The powers of flexion of the wrist and adduction of the thumb were considerably increased, but there was no sensation as yet over the ulnar distribution.

He did not resume work till March, 1891, not because he was unable to undertake light work, but because he wanted to give the arm a fair chance of complete recovery. Since March, 1891, he had not missed a single day's employment, and was able to do all his duties completely, from wheeling a well-laden barrow to using a scythe.

When the patient was seen in February, 1896, there was a firm round scar along the inner side of the arm. The circumference of the right forearm was eleven inches; the left forearm, eleven inches and an eighth; the right wrist, seven inches; and the left wrist, seven inches and an eighth.

From these measurements, says the author, it will be seen that the muscles had almost completely returned to their former volume, and in the hand all the muscles except the abductor of the thumb were as well developed as in the left, this being quite as well marked in the interossei as in the other muscles. The movements of the arm were completely restored and were almost as perfect as in the left. Flexion of the fingers and the grasp had completely returned, and the only weak muscle was the abductor of the thumb, which had no perceptible power. Sensation was completely restored, as was easily demonstrated by touching the different portions of the arm and hand with a pin. All the muscles of the arm and hand reacted to faradism, except the abductor of the thumb.

It will thus be seen, says the author, that, although recovery had been tardy, it was complete in almost every respect, the only exception being that of the abductor pollicis, which for some unexplained reason did not recover its function. The case, he says, clearly demonstrates the possibility of restoring continuity of nerves by grafting. Whether the spinal cord in this case took up the functions of a nerve, or whether it simply served as a basis on which the nerve tissue was built up, the author is unable to say, or why restoration of function in the ulnar nerve should have been slower than in the median nerve, as the ends of the ulnar nerve were not separated more than three quarters of an inch, whereas the ends of the median nerve were from two to three inches apart. Could it be, he asks, that the spinal cord offered a better medium for establishing continuity? Mr. Robson thinks there is still much to learn concern-

ing the repair of nerve lesions, and states that he is not at all certain that the conclusion of physiologists is correct when they affirm that the peripheral portion of a divided nerve always undergoes atrophy.

**The Infant's Bath.**—In the November number of the *Archives of Pædiatrics* there is an article on this subject in which the writer remarks that the bath is the most essential item in the hygiene of infancy. Its proper administration is so important to the well-being of the child that instruction regarding it should always be given by the medical attendant. The changes which take place at birth are so radical that the first bath should be given with great care. The child is suddenly transferred from an unvarying temperature of 100° F., where surface evaporation is impossible, to a varying temperature of from twenty to thirty degrees lower, where evaporation from surface and lungs is constant, and where it must rely wholly upon heat generated within its own body. It is remarkable, he says, that such a change is as well tolerated as it is: We should certainly do nothing to reduce the vital forces, and should take every precaution for preserving the vital heat. The temperature of the water should be decidedly higher than that used subsequently. The first bathing should be done as rapidly as possible. The tub is not necessary, and, in the case of delicate children, it is unwise to use it.

The *vernix caseosa* is soluble in fat, which should be employed for its removal. An animal oil is best; lard removes it more readily than any other substance. After thorough anointing of every portion of the body, especially the folds and creases, the oil should be wiped away with a soft towel, a sponge with a little warm water and soap being used in places. On the following day, when the child has become more accustomed to its new surroundings, a more thorough bath may be given, but it is best not to use the tub until the cord has fallen.

When the tub is first used, the period of immersion should be short. The nurse should take the child upon the lap, where it is carefully soaped and sponged, care being taken to avoid drafts and undue exposure. It may then be dipped into the water, more for the purpose of rinsing than for actual bathing. The duration of the immersion may be increased until the whole bath is given in the tub, this being determined by the strength of the child and its power to react.

A healthy child of ordinary strength should be bathed daily until it is at least two years old. The bath should be given midway between meals, the late morning or forenoon being the most suitable time. In hot weather the child may also be sponged in the evening. Washing for purposes of cleanliness should be done as frequently as the occasion may arise.

Cold baths, continues the writer, should never be given to an infant, and all attempts at "hardening" should be strictly forbidden. A cold bath accomplishes good only when the shock it produces to the cutaneous surface is followed by brisk reaction. Little children are very susceptible to cold; reaction is slow and imperfect. Hence, if the bath is too cold, the child remains pinched and blue, and is restless and fretful. If such baths are frequently repeated, the child becomes continuously irritable and ceases to thrive. Very serious results may immediately follow excessive chilling of the surface. Too hot baths, on the other hand, should be avoided with equal care.

The hand is an unsafe guide by which to determine the temperature of the water. This should always be determined with the thermometer. A bath thermometer should, therefore, be a part of the equipment of every nursery. This consists of an ordinary thermometer of large size, set in a wooden case. The proper temperature of the bath for various periods during the first two years is as follows: At birth, 100° F.; during the first month, 97°; from one to six months, 95°; from six to twelve months, 90°; and from one to two years, 86°.

The soap employed for the baby's bath is of importance. Soap containing an excess of alkali may seriously irritate a child's delicate skin and predispose it to erythema or eczema. The best grade of white Castile soap is the most suitable for baby's use. The oatmeal soap, of a good maker, may also be employed. Dr. Griffith regards the German soap known as *Basis Seife* as the best. It can be obtained through most druggists.

The writer thinks that a dusting powder is not necessary when the skin is in normal condition and is properly dried after the bath. One of the chief objections to its use, he says, is the fact that nurses are prone to rely upon it, instead of taking proper care in drying the surface. When properly used, there can be no objection to it. In the case of some children it is a necessity. Talc is the best powder for infants' use, but lycopodium, rice powder, magnesia, and starch are almost equally good. If the child shows a particular tendency to chafe, a powder may be prescribed consisting of two drachms of subnitrate of bismuth or powdered oleate of zinc and an ounce of powdered starch.

If the child becomes afraid of the bath, it is unnecessary cruelty to insist on its being plunged into the water. Such fear, if once acquired, is very difficult to overcome. The best means for accomplishing that end is to place a sheet over the tub and gradually lower the baby and the sheet into the water.

The scalp should be washed daily until the child is six months old. After that time the frequent application of soap and water tends to render the hair brittle, and their too frequent use is not advisable.

The details of the infant's bath, of which an excellent illustration is given, are considered by the writer as being very important, for without extreme care in protecting the child's body from cold, harm of a more or less serious nature may result. The nurse, he says, should have a small rubber sheet, or, better still, a rubber apron, for her own protection. Over this should be spread a double bath blanket in which the child may be protected while being dried. A still better device consists of two large pieces of flannel buttoned or sewed to the waistband of the nurse like an apron. The lower one may be used to hold the baby in, and the upper one to cover it while the towels are being used.

The character of the bath tub is also of importance. An oval tub of tin or porcelain with one sloping end is serviceable. Such a tub should be placed on a low stand or table, to save unnecessary strain upon the back of the nurse, and to diminish the danger of accidents to the child by its slipping from the hands. A portable bath tub of folding pattern is a great convenience. It can be readily put out of the way at home, and is easily carried abroad, so that the infant need not be deprived of its bath if traveling is necessary. A home-made tub of folding pattern was described not long since in *Babyhood*. The legs, which are crossed, are

thirty inches long. These are attached to two side bars at the top. The tub itself is made of a single piece of white rubber cloth. There is a hem in each end, and through these hems broad tapes are passed and securely fastened to the ends of the side bars. The sides of the rubber cloth are tacked to the top of these side bars; a small plate at each corner gives the tub its shape.

The writer thinks that it is so important that the infant should receive its bath regularly and in proper manner that the family physician should never feel it out of his sphere or beneath his dignity to give minute directions regarding it.

**Mirror-writing.**—In Parts LXXIV and LXXV of *Brain* Dr. F. J. Allen, of Birmingham, England, remarks that a study of the subjective phenomena of left-handed writing, or mirror-writing, may help to throw light on the nerve processes concerned in writing and other complex co-ordinated acts. The faculty of mirror-writing is probably not at all rare. It may be possessed more or less by most persons, but may remain unobserved. It is apt to be discovered for the first time when some nerve disease renders normal writing difficult or impossible; the patient then falls back on the resource of left-handed writing. Thus mirror-writing is often a symptom of nerve disease; but the disease need not be the cause of the existence of the faculty, but only the cause of its discovery. The author states that he accidentally discovered it in himself when he was a boy, and that, on making the first attempt, he was able to write backward with the left hand without error or hesitation. The most noticeable subjective phenomena, he says, are the following:

1. It is very easy to write in mirror fashion with chalk on a blackboard, co-ordination seeming to be perfect in the movements of the left arm and wrist. But when using a pen with the left hand there is slight difficulty in some of the movements. There is no hesitation as to the formation of the letters, but occasional awkward movements will produce distorted lines, and there is special difficulty in keeping up a smooth onward movement, the movement of alignment.

2. Writing is only a little slower with the left hand than with the right. In the fastest possible mirror-writing there is no error in the form of the letters—only such want of neatness and distinctness as occurs in writing too fast in the ordinary way.

3. The following actions are quite easy: Writing the same thing simultaneously with both hands. Writing backward with the left foot, *i. e.*, scratching on sandy ground, as one sometimes does with the right foot. Using the deaf-and-dumb finger alphabet in the reversed or left-handed manner.

4. If a new alphabet is learned with the right hand, it can be written with the left; it is not necessary to learn it separately with the left hand; the nervous system, after being trained to any kind of writing with the right hand, is able to send its co-ordinated messages almost equally well to either hand.

5. The assistance of sight is not necessary in mirror-writing. Indeed, sight may even impede it; and, although it is easy to write left-handed, it is difficult to read what one has written. The author states that when he looks at his mirror-writing, it sometimes conveys no meaning to him, and he experiences sensations which are probably much the same as those of a person who is word-blind, but retains the faculty of writing. In order to decipher such writing, he says, it is necessary

to run the eye along the lines, and so reproduce the sensations which accompany the act of writing. He finds considerable difficulty in reading print reversed by means of a mirror, but hardly any difficulty in reading a book held upside down.

Dr. Allen states that he has no tendency to be left-handed, though he might almost be called ambidexter.

The sensations accompanying all kinds of writing, he continues, whether with right hand or left hand, right foot or left foot, are so similar as to suggest that in all cases the messages start from the same region of the brain; but it seems as if a series of commutators existed at a lower level whereby the impulses could be turned into different channels leading to analogous but sometimes heteronymous groups of muscles. This supports the view that the true graphic centre is not coincident with either of the motor centres, but superior to all of them.

**The Treatment of Whooping-cough by Inhalations of Ozone.**—In the *Nord medical* for November 1st M. E. Doumer relates his experience with this mode of treatment in five cases. The general condition of the patients was satisfactory, except in the case of a child of four years, who vomited frequently and had several attacks of epistaxis. Generally, the nights were disturbed by attacks of coughing, with the exception of the case of an adult in whom the disease was very slight. The age of the patients varied from three to thirty-five years. They were subjected to inhalations of ozone for ten or fifteen minutes twice a day, and the general results observed were as follows: 1. Four of the patients who passed very bad nights became better from the second day of the treatment. 2. The frequent vomiting attacks in the fifth patient disappeared after the beginning of the treatment. 3. From the second day the coughing attacks became less frequent and less painful. 4. Whenever the treatment was interrupted the attacks of coughing had a tendency to return in greater number. 5. All the patients recovered after a period of from nine to fifteen days, during which time they received from twelve to twenty-seven inhalations of the ozone. 6. This treatment was begun in the middle of August, and up to the time of the report there have been no relapses.

M. Doumer states that he recognizes the fact that this report is based upon a very small number of cases. Caillé, of New York, he says, reported seven cases, and M. Labbé and M. Oudin fourteen or fifteen cases in which rapid recovery was obtained with this mode of treatment. Such results are very encouraging, says M. Doumer, and it will be interesting to pursue the study of this mode of treatment.

**The Heart under Roentgen Illumination.**—Dr. Benedict, of Vienna (*Wiener medizinische Blätter*, October 29, 1896), finds by X-ray illumination that the apex approaches the base of the heart in systole, so that there is no apex impulse in Skoda's sense, but at most a lateral systolic apical stroke. The ventricles are not entirely emptied at each systole, but always retain a considerable amount of blood; nevertheless, the four thousand heart-beats to the hour carry fresh blood enough into the arteries. On deep inspiration, the normal heart rises from the diaphragm, so that an appreciable interval is visible between them. Such examinations are most satisfactory if made on young and thin persons, and they do no harm unless they are made improperly or too often.

AIDS IN OBSTETRIC TEACHING.  
By JAMES CLIFTON EDGAR, M.D.

(Continued from page 674.)

III. Composition Models.

In casting about some time since for a cheap substitute for rubber in the construction of models, our atten-

tion was directed to the glue composition which modelers and plaster workers have for years made use of in the manufacture of their interior decorations. Our aim was to produce flexible cervixes and pelvic floors by this method, and after much experimenting we were compelled to confine our models in composition here described to a series of parturient cervixes in different

stages of dilatation (Figs. 38 to 43), and, after all, fall back on rubber for the pelvic floor (Fig. 63).

The composition mixture finally adopted was one of Cooper's A-1 glue and pure glycerin, the same as that used by modelers and plaster workers, with the addition of glycerin, to give the mass lasting flexibility, the glue being chosen in preference to gelatin because of its being cheaper. The proportion of the glue and glycerin will depend upon the degree of flexibility of the model desired. I have found that a proportion of one part of glue to one of glycerin gives the proper flexibility to the mass for the cervixes subsequently described.

The method is very simple and, aside from the glycerin, very cheap. The glue is first soaked in cold water until moist; the excess of water is then removed by filtering through stout burlap or other filtering material. Then, placed over a water bath, the glue is melted, the glycerin added, and the mass allowed to boil until most of the small amount of water contained in

it is expelled. Subsequent contraction and hardening of the model will depend upon the completeness with which the water passes off at this time. The time required for this heating process will depend upon the size of the mass and the amount of the contained water.

When ready to pour, the mass should be almost free from water, of a thick, creamy consistence, and no small pieces of glue should remain unmelted.

At this time any desired color may be imparted to the composition by the addition of a strong alcoholic solution of any of the aniline series.

*Preparation of the Mold.*—Given a clay, plaster, *papier-maché*, or other model, which it is desired to reproduce in glue composition, it is first necessary to construct a mold. For the composition cervixes (Figs. 38 to 43) the lower segment of the *papier-maché* model of the pregnant uterus at the eighth month (Fig. 18) was used. A negative mold of the lower third of this uterus was taken in plas-

FIG. 45.—Digital dilatation of the parturient os. Os admits one finger. Vaginal and supravaginal portions of the cervix present. (Composition model, from a photograph.)

ter in the usual way. Then, to secure the desired thickness of the composition model, a layer of clay of the required thickness was carefully placed in the negative mold, completely and smoothly lining it. Plaster is now run in over the clay to form the core of the interior of the mold. The plaster being thoroughly hard, the core and negative mold are separated, the clay removed from the negative mold, both carefully shellacked upon their opposing surfaces, and when dry are oiled and fastened firmly together. The mold is now ready for the reception of the heated glue mass.

*Pouring the Composition and casting the Model.*—In pouring the mass care should be used that it is not too hot, otherwise it is liable to stick to the mold and core by removing the coating of shellac therefrom. Moreover, we have found that the higher the temperature at which the mass is poured the greater will be the subsequent contraction of the model upon cooling. At ordinary temperatures the models should not be removed from the molds for at least six hours.

FIG. 46.—Bimanual dilatation of the parturient os. Os admits two fingers. Vaginal and supra-vaginal portions of the cervix present. Commencing shortening of the cervical canal. (Composition model; from a photograph.)

FIG. 47.—Bimanual dilatation of the parturient os. Os admits three fingers. Supravaginal portion of the cervix disappearing. (Composition model; from a photograph.)

I have not found it necessary in these obstetric models to keep them when not in use in their molds to avoid distortion, as Freeborn\* advised in pathological models.

*Remelting the Models.*—Should the models, after continued use, shrink or become hard, remelting and adding an additional quantity of glycerin to the mass will lend new flexibility to the models and render them less liable to shrink.

I desire to express my indebtedness to Mr. James M. Kerr, of the firm of Kerr & Rasario, sculptors, 229 West Thirty-second Street, New York, for valuable instruction and assistance in the use of plaster and composition for the purpose indicated in this paper.

1. Series of composition models of lower uterine segment, showing mechanism of dilatation, with the gradual disap-

\* Freeborn. A New Material for Models. *Proceedings of the New York Pathological Society* for 1891.

FIG. 48.—Bimanual dilatation of the parturient os. Os one-half dilated. Lateral position of the hands. (Composition model; from a photograph.)

pearance of the supravaginal portion of the cervix.

Figs. 38 to 43 represent these composition cervixes, and we have added, to render the illustrations more graphic, an outline sketch of the upper vagina and cervix of each to indicate the changes in cervical canal, external and internal os, as dilatation progresses.

The uses to which such simple composition models can be put are almost endless, and we have illustrated some of these in the following illustrations:

FIG. 49.—Bimanual dilatation of the parturient os. Os two-thirds dilated. Antero-elevation of internal os. (Composition model; from a photograph.)

*Bimanual Dilatation of the Parturient Os.*—Series Figs. 44 to 50 indicate our preferred method of combined instrumental and bimanual dilatation of the parturient os. The limits of the present paper forbid my entering upon the arguments in favor of this particular variety of manual dilatation, which has been given an abundant trial over a period of several years in many conditions of the parturient cervix.

I feel justified, however, in stating in this place that this method of bimanual dilatation of the os is to be preferred to other digital and instrumental methods, because (1) the membranes are preserved throughout the operation or until full dilatation is ob-

FIG. 50.—Bimanual dilatation of the parturient os. Os fully dilated and being stretched to prevent accidents to the after-coming head. (Composition model; from a photograph.)

tained; (2) there is no interference with the original presentation and position; (3) the sense of touch of the operator's fingers is unimpaired; (4) there is no constriction of the operator's hands; (5) the amount of force exerted upon the external ring can be better estimated, and hence there is less likelihood of lacerations occurring.

Fig. 51 represents the position of the fingers at the ring of the os in bimanual dilatation; no encroachment into the uterine cavity occurs.

Fig. 52 shows the position of the hands as seen in

FIG. 51.—Bimanual dilatation of the parturient os, internal view, showing position of the fingers. Os admits three fingers readily. Internal os still present. No encroachment of the fingers upon the cavity of the lower uterine segment. (Composition model; from a photograph.)

an operation on the living subject, and is from a photograph taken at the Emergency Hospital.

*Ordinary Digital and Manual Dilatation of the Parturient Os.*—Figs. 53 and 54 represent the ordinary digital (with one hand) and manual dilatation of the os, in both of which methods there is unnecessary and dangerous encroaching on the part of the operator's hand upon the lower uterine segment and the consequent dangers of (1) displacement of presentation or position; (2) displacement of arms or cord; (3) premature rupture of the membranes, and loss of the valuable assistance of the liquor amnii in subsequent manipulations, as version, for instance; (4) premature separation of a placenta prævia; and (5) constriction and loss of sensation in the operating hand, and with the consequent danger of lacerations of the external ring from inability to measure the amount of force exerted and the tension of the ring, together with failure to completely paralyze the ring, so that trouble in the extraction of the after-coming head results.

FIG. 52.—Bimanual dilatation of the parturient os. External view, showing position of hands. (After a photograph of the operation taken at the Emergency Hospital.)

FIG. 53.—Illustrates a common method of manual dilatation of the parturient os and the dangers that ensue of prematurely rupturing the membranes, displacing the presenting part or separating a placenta praevia, by reason of the marked encroachment of the fingers of the operator into the cavity of the lower uterine segment. (Composition model; from a photograph.)

FIG. 54.—Illustrates a common method of single-handed manual dilatation of the parturient os, which has the same objections as the method depicted in Fig. 53, but to a less degree. (Composition model; from a photograph.)

FIG. 55.—Barnes's bag in position in a cervix that admits two fingers. Show encroachment of the distal end of the dilator into the cavity of the uterus and the possible dangers of displacement of the presenting part, or premature separation of a placenta praevia, and consequent internal or concealed hemorrhage. (Composition model; from a photograph.)

FIG. 56.—Dangers of breech extraction through an imperfectly dilated os. Same as Fig. 55. Seen from the uterine cavity. (Composition model; from a photograph.)

FIG. 57.—Dangers of breech extraction through an imperfectly dilated os. External os not fully dilated. Traction on the legs causes extension of the head and both arms. Seen from the vagina. (From a photograph; composition model.)

Fig. 55 shows the interior of the lower uterine segment, with an os the size of two fingers, a Barnes's cervical dilator in position, and the dangerous encroachment of the latter into the cavity of the uterus, rendering malpresentation liable to occur.

*Dangers of Breech Extraction through an Imperfectly Dilated Os.*—Figs. 56 and 57 illustrate this condition, selected from many other equally important ones.

When the student is made to see what may happen

FIG. 58.—Cervix partially dilated. Membranes ruptured. Vertex presenting. Prolapse of hand and cord. (Composition model; from a photograph.)

FIG. 59.—Cervix partially dilated. Labor obstructed by reason of partial extension of the head, causing occipito-frontal diameter to pass through cervix and pelvis. (Composition model; from a photograph.)

should he thoughtlessly make traction upon a leg in breech presentation before the completion of the first stage of labor, he is not likely to forget the dangers of such manipulations in the extended head and arms and the resulting impaction and death of the fetus.

Fig. 58 represents prolapse of the cord and hand in the middle of the first stage, and its accompanying dangers to the fetus; and Fig. 59 illustrates a common cause of obstructed labor due to an imperfect attitude of the fetus. The chin has left the sternum, resulting in incomplete flexion of the head and the passage of a larger diameter than necessary (occipito-frontal) through the cervix and pelvis.

(To be concluded.)

#### A NOTE UPON

#### SERUM DIAGNOSIS BY MEANS OF DRIED BLOOD SAMPLES IN (EXPERIMENTAL) CHOLERA.

By WYATT JOHNSTON, M. D., AND E. W. HAMMOND, MONTREAL.

(From the Molson Pathological Laboratory, McGill University.)

THE announcement made by Achard and Bensaude (*La Presse médicale*, September 26, 1896; abstract in *New York Medical Journal*, November 7, 1896) that they had successfully employed serum diagnosis in all of eleven cases of cholera, has led us to publish briefly the result of some experiments we have been making to see if drops of dried cholera blood form a suitable material for obtaining and testing the serum reaction. Not having the blood of cholera patients at our disposal, we experimented on rapidly immunized guinea-pigs.

We find that when the blood serum of an animal gives a good reaction in the fresh state the reaction may also be obtained by moistening a drop of the dried blood with water and mixing it with an actively motile cholera culture.

The cholera culture employed was one isolated by Dunham in 1892 from a case in New York and transmitted to the laboratory in 1893 by Professor Welch, of Johns Hopkins. This was brought up to a high degree of virulence by passing it through a series of guinea-pigs until intraperitoneal injection killed in ten hours, and subcutaneous injection in twenty hours.

From a tenth to half a loopful of sterilized suspensions of a twenty-hour growth in agar was injected beneath the skin or into the peritonæum of guinea-pigs, and was followed by prompt loss of weight. The larger doses usually produced promptly the characteristic blood reaction in the course of a few days, varying in intensity with the different animals.

The reaction was found well developed in one case within three days and a half after the dose. Here the animal died from a secondary infection. The dried blood, first examined two days after the animal's death, gave the reaction to perfection, extensive clumping taking place in the momentary interval between mixing the drop of dried-blood solution with the culture and bringing it under the microscope. Positive results were obtained in the cases of two other guinea-pigs inoculated on the same day. Check examinations of healthy animals and of these inoculated with very minute doses gave negative results.

From this it appears that the sending of samples of dried blood is likely to suffice for the serum test. We hope before long to receive samples of dried cholera

blood sent us under conditions which will be such as to give the method a practical test.

The fact that Achard and Bensaude found the reaction present even as early as the first day (in non-fatal cases) should make it invaluable in the diagnosis of cholera.

We have been surprised to find the ease with which the typical serum reaction, though not complete immunity, could be induced in animals by even a single dose of typhoid and cholera culture.

A preliminary protective dose is not strictly necessary, but it guards against loss of the animals by an accidental overdose.

We have followed Pfeiffer's recommendation to wait until the loss of weight of the animal is made up before repeating the dose.

## THE COMMITMENT OF THE INSANE

### AND THE

### "INSANITY LAW" OF THE STATE OF NEW YORK.\*

By GEORGE W. JACOBY, M.D.

THAT room for improvement existed in the laws governing the care of the insane in the State of New York had been so often asserted, and to an extent also substantiated, that the cry for reform was heard on all sides. Much, very much, has been since accomplished through the principle of State care and by the energetic and progressive action of the State Commission in Lunacy; as much as this is to be lauded, so much, however, must it be deprecated that in important matters, when questions arose which concerned both therapy and legislation, no unity of opinion even in regard to fundamental principles could be obtained, so that in certain quarters that was looked upon as the ideal to be attained which in others was considered an unpardonable regression. That under such circumstances any reorganization of our laws must result in more or less of a compromise was to be foreseen. In the case of the insane, the jurist and the physician necessarily meet, and each one involuntarily tends to view the entire situation from his own point of vantage. This, notwithstanding that in medical jurisprudence, a dual and border territory of two heterogeneous sciences, the recognition of truth is only then possible if all concurring juridical and medical aspects are impartially and carefully considered, as if the jurist were a physician and the physician a jurist. Such an impartial and actual consideration would easily disclose which side of a question, the medical or the legal, naturally preponderates, and to what extent such is the case. Unfortunately, however, the individual jurist and the individual physician is far too slightly familiar with the other's science to enable him to undertake such impartial consideration. It is, how-

ever, not too much to demand at least such an amount of objectiveness that each, the physician as well as the lawyer, should recognize that his territory must at some point or other have its limit, even if he is befogged as to the extent of this limitation, and that, therefore, he must not absolutely ignore the fundamental principles of the other.

The necessity of being obliged to collaborate with the exponent of a science which to me is more or less foreign, in order to attain a common end, one which rises superior to the individual interests of either of us, makes it imperative for me, at least, to endeavor to show toward the science of my collaborator such an amount of interest as to enable me to receive from him the elementary instruction necessary for an understanding of the views which he advocates.

By such principles do I consider myself bound when I am called upon to judge of the attitude of any and every worker, be he jurist or physician, in the tangled domain of medical jurisprudence. On account of the eminent difficulties of such collaboration between the two sciences, law and medicine, the results attained may never contain the ideals of both representatives, but if only the basic principles of each science are not willfully ignored, an acceptable understanding may be reached.

The endeavors to reorganize the care of the insane in the State of New York have formally reached a temporary close in the enactment by the Legislature of the New York State law which, under the name of the "Insanity Law" (chapter 545 of the Laws of 1896 and chapter 28 of the general laws of the State), went into effect on the 1st of July of this year.

One of the chief changes that were made in the former law applies to the commitment of the insane to institutions. Reform in this procedure of commitment has been frequently and strenuously advocated, but that the term "reform" is a characterization which may fittingly be applied to this new enactment we all—for I believe I may speak for every physician who has had any experience in the commitment of the insane—must emphatically deny.

In my opinion the framers of this law have totally failed to accomplish their mission—that, namely, of uniting the postulates of jurisprudence with those of medicine—and thereby, considering the decisive influence which medical jurisprudence has upon public welfare, have acted detrimentally to such welfare. The object of the following disquisition is to adduce the proofs which have led me to this opinion. I will be as brief as possible, but the subject requires a certain amount of detail.

The first impression gained upon reading the new law and superficially comparing its provisions with those of the old law, is that the framer has followed a preconceived tendency to as far as possible ignore the medical side of the question. To facilitate comparison let us briefly sketch the provisions of the old law:

The first step necessary in order to commit a person

\* Read before the New York Neurological Society, October 6, 1896.

to an institution under the old law was the making out of a certificate of insanity by two specially qualified physicians. The certificate could be made only after a personal examination of the patient. The special qualification of the physicians consisted in their being graduates of an incorporated medical college, in having been in active practice for at least three years, in being permanent residents of the State of New York, in being of reputable character, and in these qualifications having been certified to by a judge of any court of record. Upon a certificate of two such physicians the temporary detention in an institution could be effected—the temporary detention, for upon such a certificate the patient could not be held for more than five days. In order then to make the detention a more permanent one, it was necessary to apply to a judge of a court of record in the city and county or in the district in which the patient resided for approval of this certificate. Before giving his approval or refusing to do so, this judge was empowered to institute inquiry and take proofs as to any alleged lunacy, and to call a jury in each case to determine the question of lunacy if in his discretion such action was necessary. Only if the judicial approval was obtained within ten days after the date of the medical certificate could the detention of the patient be prolonged beyond the five days referred to. Therefore, according to the old law, the commitment to an institution presupposed (1) a certificate of two physicians, which, when sworn to before a notary, in itself sufficed for a detention of five days; (2) a judicial act consisting in approbation of the medical certificate with or without antecedent process of proof.

The new law has retained these two provisions in so far as it also requires a certificate of two physicians and a judicial act, but it has materially changed these provisions, not only in their constitution and action, but in their relation to each other. So materially has the entire pivot been displaced that, instead of an approved medical certificate, we now have a judicial decision with antecedent medical affidavits; an act of medical care has been supplanted by a legal process not at all lacking in formalism.

To begin with the medical certificate, the new law has made hardly any change in the provision for its construction. Now as formerly it must be made out under oath by two physicians whose qualifications remain the same; only, the necessary personal examination of the patient must be made by both physicians at one and the same time; also it is now ordered that the certificate must bear the date of this combined examination—i. e., the certificate must not be based upon the results of any previous examination of the patient, even should such examination antedate the certificate by only a single day. Whereas, according to the former law, the certificate in itself (without judicial approval) sufficed for the temporary detention in the institution, this force has with the new law been lost.

The judicial act of the old law has completely changed its nature in the new one. The judicial approval has totally disappeared and has been replaced by an independent judicial order. It is now the judge who, by power of his official authority, declares a person standing under his jurisdiction deprived of his liberty; it is not any more the physician dealing with a patient whose freedom, in his opinion, would be a menace to himself or his neighbors. With this, however, the responsibility for the act has been removed from the shoulders of the physician to those of the judge; from a question chiefly medical, has been made a question chiefly legal. This probably explains the further condition, that the rapid action which was formerly possible is now hampered by a delaying legal apparatus, which, while in the abstract not always necessary, will practically be employed more or less unexceptionally. For it is not any more a question of a helpless person unable to look out for himself on account of having become insane, but of a citizen who is to be injured by an infringement upon his personal liberty. If we pass over the provisions of the new law as to who is qualified to apply for the commitment as being immaterial and inconsequential, we may describe the manner of such commitment in the main as follows:

1. *The Application.*—The application for commitment must be made in writing and addressed to a competent judge. Competent is the judge of any court of record in the city or county, or of the Supreme Court of the district in which the patient resides or is. The application must, in addition to the name, age, residence, etc., of the assumed patient, contain—

- (a) The facts upon which the allegation of insanity is based and the reasons for the necessity of commitment.

- (b) The petition to the judge for a declaration that the person is insane, and for an order committing him to an asylum.

- (c) The name of the institution to which the commitment is intended.

- (d) The declaration on the part of the petitioner of the belief that this act is in the interest of the patient.

2. *The Verification of the Application.*—The applicant must be duly sworn, and declare the assertions contained in the petition to be true, and the matters stated upon information and belief to be true in his opinion. A copy of this notarial oath is to be affixed to this application.

3. *The Notification, or Surrogation of Notification.*

- (a) *The Notification.*—At least one day prior to the presentation of the petition to the judge the patient must be personally informed of the proposed application; under certain circumstances such service must be made also upon certain relatives, or, these failing, upon persons residing in the same house.

- (b) In cases in which such personal notification of

the patient seems to the petitioner to be impracticable, he must so inform the judge to whom he intends to present the application. If the judge, nevertheless, considers the personal notification indicated, this service must be made, or the entire action becomes fruitless. If, however, he has satisfied himself of the existence of such impracticability, he may at once either dispense with the personal notification (neither the patient nor any one in his stead being notified) or he must designate some person who is to be notified in lieu of the patient. The reasons for such dispensations with personal service the judge must give in writing. This is to be affixed to the application.

4. *Definitive Application.*—If the judge does not dispense with personal service upon the patient, the definitive application can only be made upon the day following such notification; if such dispensation is granted, there does not seem to be any reason why the application should not at once be formally made. The medical certificate, must, of course, also form part of the application.

Now, after these requirements have been fulfilled, and the application with the necessary documents of which it is made up are definitively placed before the judge, a decision upon the application may be at once rendered, or various legal intermediary stages, in the form of hearing of testimony and court proceedings, may defer this decision.

5. *Intermediary stages between definitive application and decision.*

(a) *Proceedings.*—Upon demand of a relative or near friend of the patient, the judge shall issue an order directing the hearing of such application before him.

This he may, however, also do if he sees fit without such application. The time set for these proceedings shall be not later than five days from the day of such order; but so far as I can see there is no reason why the proceedings may not be adjourned to some later date if regular court business so requires. If unable to conduct the hearing himself, the judge may appoint a referee, who shall then report to him. The persons directly interested, as well as such others as the judge may designate, are to be notified of the day set for the hearing. At this hearing testimony is to be taken, and if considered advisable the patient himself is to be examined.

(b) *Taking of Additional Testimony.*—Where there is no application for the order of a hearing, the judge may himself of his own incentive require additional proofs to those furnished by the application and the medical certificate.

(c) *The decision of the judge may be given at once if no hearing has been ordered, based simply upon the application accompanied by the physicians' certificate. If the order is refused, the reasons for such refusal are to be given in writing. The order may be granted in the sense of the application—the patient being declared insane and committed to an institution—or the order*

may be modified, the patient being declared insane, but instead of being committed to an institution be committed for care and protection into the charge of some relative, friend, or guardian; this, if the patient appears harmless and the relative, friend, or guardian declares himself willing and able to assume this responsibility.

6. So far as the actual internment is concerned—*i. e.*, the execution of the judge's order of commitment—I will here only say that the above-mentioned documents—application, certificate, order of proceedings, decision, and order of commitment—must immediately after the latter has been given be sent to the superintendent of the institution, and that this superintendent may refuse to receive the patient, not only because in his opinion he is not insane within the meaning of the statute, but also because the above-mentioned papers, in his opinion, are not executed in accordance with the legal provisions. Furthermore, reception is forbidden if more than five days have elapsed since the order was signed.

7. Let me further remark, in order to be complete, that an appeal may be taken against the decision of the judge by either party, and that such decision then involves a trial by jury.

Such, then, is the proceeding which the new law has elaborated for the commitment of the insane. That single jurists will in this proceeding find a source of satisfaction I do not doubt; but that a physician from a medical point of view can become reconciled to it is to me inconceivable. It must be clear that the requirements which medically are demanded of a proceeding whose purpose is to care for an individual, whether for his own protection or that of society, are not fulfilled by this law. A law stands scientifically higher the more perfectly it is adapted to the practical conditions of life, whose necessities it should serve, and it is totally immaterial what these conditions of life or necessities represent in each concrete case; immaterial, therefore, whether we are actually dealing with the organization of a standing army, with protection to capital or labor, with the building of means of transport, with the public-school system, or with the care of the sick and infirm. All such conditions or necessities of life must be aided by the law—*i. e.*, laws—and a legal apparatus must be constructed for the formation and maintenance of such organization. In all such cases the jurist's activity as a jurist begins, and it is not in the least my intention to maintain that in so far as the construction of laws is concerned his task is merely a formal one, as though his task were only to discover the best external form for a law, while the actual contents did not concern him; on the contrary, I am thoroughly well aware that every question which affects organized society in any of its functions also substantially falls within the territory of the jurist. It is, however, another question how far in each single case this territory extends, and here we must say that the extent of the jurist's influence upon the material contents of the law will necessarily vary

with the nature of the subject in hand, and necessarily always only be a relative one. If, therefore, the function of a law is to be subservient to practical conditions of life, it follows that those who possess the greatest knowledge of the special conditions which a certain law is to serve should be allowed to exert the greatest influence upon the construction of such law. No one will deny that a law concerning our coast protection should correspond to the expression of opinion of the experts in military and naval affairs. Should matters be different when a law concerning the care of the insane is in question, simply because so many laymen discuss mental diseases with arrogated authority, but without the slightest trace of even the most elementary knowledge? If, furthermore, a law is necessarily better the more it gives reflection to expert opinion upon the corresponding subject, so every true jurist will, in the construction of a law bearing upon any subject in which he is not an expert, endeavor to show consideration for the principles set up by those learned in this subject.

In order to avoid the possibility of any misinterpretation, I wish here to specially state what is perhaps self-evident, that in the present consideration I have in mind only those provisions of the new law which have reference to the actual commitment to an asylum, and therefore not those which regulate the appeal from the order of commitment, nor just as little the other, in part admirable, contents of this law. The old law was in its main provisions much to be preferred—first, in so far as it allowed for the temporary care of a patient upon the medical affidavit alone. In especially acute cases this provision was of inestimable value for the patient as well as for his surroundings; then the old law, at least in so far as its text was concerned, was superior to the new one in not demanding so formal a course of proceeding as the new law involves as a regular course.

The provisions of the new law which we are now considering were the outcome of complaints on the part of the public, oft repeated during the last few years, that perfectly sane people, or those only odd or eccentric, were confined in institutions by relatives to whose egoistic interests their presence formed an obstruction, aided by the "ever-ready tendency of physicians to diagnose insanity in every deviation from the ordinary."\*

Actually, however, notwithstanding the most thorough and impartial investigation, not a single case of confinement of a sane person in an asylum could be unearthed, but, on the other hand, many cases are known to us all in which the jurist, voicing the skepticism of the public, has brought about the premature discharge of insane persons, to the irretrievable ruin of themselves and their families. Notwithstanding the repeated proof of such facts, the deeply rooted suspicion still flourished in certain circles and was artificially nurtured and disseminated by the indiscriminate efforts of parties not without a large share of legislative influence.

Thus this suspicion has received faithful expression in the one-sided regulations of the new law. While the old law was by no means an ideal one, it at any rate was "pure in intention, good in principle, and wise in its disposition," and even when enforced in the most literal and annoying manner, as was usually the case, possessed palpable advantages over the law as it now exists. As already stated, there are two main points in which these laws differ from each other essentially, and to these I believe I am warranted in limiting myself. The one of these differences consists, as we have already seen, in the fact that in the new law the medical certificate without approval no longer possesses the power of temporarily placing a patient in an institution, but that such confinement is always coupled with a judicial proceeding. This from a medical point of view must be looked upon as a great objection to the new law. It is superfluous for me here to show how delay may react deleteriously upon both patient and surroundings.

The second main difference between the old and the new law has been shown to consist in the formal procedure which the new law has constructed in order to effect a commitment.

This procedure, which consists of certain clearly separated steps, is begun by an application, the form of which is clearly specified, and ends with a formal judicial act—an order. This act is supplied with reasons for its existence. If the application is granted, the reasons are to be sought in the attached medical certificates; if denied, they must be specially formulated in writing. Between application and decision a verbal proceeding may be interposed, this having a certain time limit. Adjournment of the proceedings is also provided for, so that actually not only one but several sessions may take place; so, also, the proceedings may take place before a referee.

It is true that also under the old law the judicial act (approval) might be preceded by a hearing, but this was purely discretionary with the judge. At present the hearing is obligatory upon demand of any relative or friend of the alleged lunatic, as well as being dependent upon the discretion of the judge. Furthermore, the formal requirements for the application as they exist to-day were absent in the old law. Above all, there was nothing about the necessity of notification;

\* Dr. Carlos F. Macdonald (*State Care of the Insane*, reprint from the *State Hospitals' Bulletin* for July, 1896), in reference to this law, says: "The writer in his official capacity has examined thousands of cases of alleged illegal detention without finding one in which the allegation was well founded. Moreover, during a period of twenty-six years of professional and official connection with the institutions for the insane in the State of New York, not a single authenticated instance of the commitment of a sane person from bad motives has come to his knowledge. And while it may be said that mistakes in the diagnosis of insanity, as in other diseases, occasionally occur, such mistakes are exceedingly rare, as shown by the hospital records, and when made, are speedily recovered and corrected."

finally, the judicial act of to-day, especially with its possible necessity of giving written reasons, can not be placed upon one plane with the old approval or the old informal manner of refusing such approval. After all this can there be any objection to characterizing the entire procedure as a piece of formalism? How obstructive such formalism may prove, if celerity in commitment is an object to be gained, every one may map out in his own mind. Of course, if the judge at the outset dispensed with every notification, if he would not require further proofs or order a hearing, and recognizing the application in its true sense would sign the order without delay, then all formalism would disappear, and very little difference between the old and the new law would exist.

But let us assume that the judge does not dispense with personal notification, or even that, in his opinion, the medical certificate is not sufficiently conclusive, and that, therefore, at least supplementary testimony should be taken. Then, of course, delay in every form is unobstructed. The faults of the new law then become so flagrant that nothing more need be said.

Now what chance is there, I must ask, that, according to the text of the law, the immediate granting of the application and issue of an order of commitment will be the regular course of procedure? In view of the spirit which is responsible for the existence of this law, and considering the number of precautionary measures which the law contains, the judge is in duty bound, if not to notify the patient directly, at any rate to do so through a third party, in order thus to preserve the essence of the law which provides for the protection of the personal liberty of the patient. Therefore I believe that the immediate granting of an application should and will be only exceptionally possible.

Of material moment, also, in considering this new law, is that from the judge's approval has been made the judge's order. This is by no means simply an alteration of name, but, as already indicated, the internment in an institution thus becomes fully and totally a juristic measure, and the province of the physician has been so constricted that the responsibility of the declaration of mental disorder does not any more lie with the physician, but does lie with the jurist. Yet, *a priori*, one would think that such internment was, in the nature of things, a medical question. Herein, also, we find a marked discrepancy between the law and the medical postulates.

If a theoretical consideration of the requirements of this law leads us to this conclusion, a practical consideration will prove to be still more detrimental to these medical postulates. With what spirit of antagonism the physician had to battle under a theoretically comparatively liberal law each of you has undoubtedly experienced. That certificates were not approved because both physicians were not personal acquaintances of the judge, although they in their certificate had

sworn to their being qualified examiners; that a judge would refuse an approval because a stuporous patient would not talk, and this fact was so stated in the certificate, which, however, called for what "the patient said"; and that a judge would refuse admission to his sanctum even, as soon as he became aware that his approval of a certificate of insanity was desired, on the ground that he "never signed such certificates," are situations in which I have been placed and in which each of you probably recognizes familiar phases.

That this spirit of opposition was a justifiable one has meanwhile been officially acknowledged by the increased stringency with which commitments are now surrounded.

The law now having become stricter, does any one believe that for this reason the judges will meet the medical views in a more liberal spirit of understanding? My experience of men and things would hardly lead me to so optimistic a conception. As especially prejudicial, when compared with the old system, we must regard the provision which takes away every method of procedure in case the application is refused, except that of appeal. This particular specification of the new law is the logical result of looking upon the entire commitment as a formal legal proceeding.

Under the informal old procedure, in case an application was refused by one judge, it was usually not difficult to find another who considered the papers perfectly satisfactory. Now, however, an application having once been formally made and refused, there remains no way of having the patient committed, except by means of a tedious appeal, which in formality even exceeds the original method of application. While this appeal is under consideration nothing can be done for the patient unless recourse is had to the police, thus knowingly placing the brand of criminality or disorder upon disease.\*

As especially characteristic of the entire law, I wish, finally, to call attention to the fact that, after all the provisions of the proceeding have been happily complied with, and the judge has "ordered" the commitment, the superintendent of the institution is empowered to refuse admission on account of any error of form in the papers.

I believe in the preceding remarks I have shown that the present law is entirely inadequate to represent the provisions which medically must exist in every commitment law for the insane.

Would that the eyes of the public could finally be opened to the fact that insanity is a disease and not a crime; that it differs from other diseases only in that in certain forms and at certain periods of the disease it

\* "Any person apparently insane, and conducting himself in a manner which in a sane person would be disorderly, may be arrested by any peace officer and confined in some safe and comfortable place until the question of his sanity be determined." The "safe and comfortable place," of course, in all such cases, is the police station.

renders the patient more or less incapable of recognizing his relationship to society, of realizing that his actions are due to disease, and of seeing the danger of his being left to his own care without danger to himself or to others. But all this does not furnish any reason why the disease should not be treated as a disease; and that the physician and not the jurist must be the one to decide whether disease is present or not, what its probable dangers are, and what mode of treatment should be pursued, is a fact which it should hardly be necessary to emphasize.

I am fully aware that personal freedom is a social right which requires the protection of the law in limitless measure, and therefore enters upon the domain of the jurist. In so far as healthy persons are concerned, I admit the jurist's exclusive sovereignty; but in disease the physician must at least be accorded a voice in the matter, inasmuch as the matter forms a specific part of his art and science.

It is certainly contrary to the nature of things to speak of endangerment of personal freedom where the ego is diseased, power of self-decision is lost, and care and control are necessary in order to enable the lost qualities to be regained. But even were it a limitation of personal freedom, by all means let this from time to time be sacrificed in order thus to save the entire personality. For precisely those acute cases for which the physician demands a rapid commitment to an institution, one unhampered by any legal formalism, are the ones in which prompt action may mean everything. These are the cases which I have specially in mind when I inveigh against the formalism of the new law.

I, personally, could find satisfaction only in such a law as would provide for the temporary (limited to a certain specified time) detention of patients, entirely unhampered by any judicial co-operation. Then as now, such certificate of commitment could be made out by two physicians legally qualified as examiners in lunacy (having practised three years, etc.), one of whom, however, should possess special psychiatric qualifications. In each individual case the relatives and the State Commission in Lunacy should be at once notified of the reception of such patient. During this period of temporary commitment free communication should be allowed verbally and by letter between the patient and outsiders, and now would, in my opinion, be the proper time for the introduction of whatever legal steps the jurist considered necessary. Finally, I will say that of course such legal steps should furnish the most ample guarantee possible against an unjustifiable prolongation of such temporary detention.

**The New York Celtic Medical Society.**—The regular monthly meeting was held on Thursday, November 26th. The order for the evening was as follows: A paper entitled *The Lymphoid Ring of the Upper Air Tract and its Relation to Health*, by Dr. Francis J. Quinlan; scientific communications, presentation of cases, and an exhibition of instruments and specimens.

## ON THE MODE OF PROCEDURE UNDER THE NEW LUNACY LAW OF THE STATE OF NEW YORK,

WITH SUGGESTIONS OF METHODS UNDER WHICH ITS PROVISIONS CAN MOST EASILY BE CARRIED INTO EFFECT, AND ALSO OF IMPROVEMENTS IN THE LAW ITSELF.\*

By RALPH LYMAN PARSONS, A. M., M. D.

THE paper recently read by Dr. Jacoby before the Neurological Society, and the discussion which followed, elicited the fact that many physicians consider the new lunacy law of the State of New York as unreasonably obstructive in its character; so much so, indeed, that some of the eminent physicians who joined in the discussion expressed the intention of hereafter refraining from placing their insane patients under legal care within the State.

If this view of the character of the law is well founded the interests of the unfortunate insane are so jeopardized thereby that the most strenuous efforts are demanded to secure its annulment or its modification.

It is a well-established fact that, as in many other diseases, so in insanity, the issue of life or death, of recovery or of lifelong mental impairment, often depends upon the promptitude with which the sufferer is placed under the most favorable conditions and under the most efficient care and treatment. And it is also a well-established fact that the promptitude with which efficient remedial measures are likely to be taken depends greatly upon the facilities which are afforded for the securing of such treatment, and on the absence of unnecessary formalities and obstructions.

Unfortunately, most persons who are afflicted with mental diseases, even in the milder forms, can be treated more efficiently and with better prospect of recovery when quite separated from their relatives and from their customary surroundings than in their own homes, however favorably situated their homes may be. But very naturally the relatives and friends of such persons are usually slow in realizing the truth and in consenting to place the invalid in the care of strangers; and the delay in taking the necessary steps is naturally increased with every additional formality and obstruction that may be placed in the way. The best condition of things, in the interest of these patients, would be the removal of all legal formalities whatever, allowing them to be placed under proper care and treatment precisely as a person ill with pneumonia or of a fever may now be placed in hospital care. But there are two special reasons which render this amount of freedom unadvisable. The first is in the interest of the mental invalid who may not understand that he is ill, or who may not be willing to submit to the needed care and treatment. In such case the will of another must needs be substituted for his own, and this requires the authorization of the law. The second reason why such free-

\* Read by title before the New York Neurological Society, November 3, 1896.

dom in placing uncertified mental invalids under compulsory care is unadvisable and even inadmissible in the interest of that great body of our citizens who are not insane; lest, possibly, some of these persons should be kidnapped and placed under restraint as a lunatic.

And it must be admitted that upon rare occasions some person who may be considered as technically sane does conduct himself in such a manner as to lead to the mistake of adjudging him a lunatic. It must also be admitted that, while these mistakes are very rare, and while the circumstances are such that serious harm is seldom if ever done, something must be conceded to the fears of a few oversensitive but influential individuals who demand protection against the possibility of such mistakes. But this concession should not be of such a nature as to jeopardize the interests of thousands of the insane in favor of a few persons whose mental status, at the best, may be considered as a doubtful one.

For example, about seven thousand insane persons are admitted to the hospitals for the insane of this State each year. Of this number, probably one tenth of one per cent. are cases in which the mental derangement proves not to be what is technically considered as insanity; as, cases of acute brain disease, alcoholism, etc.; and of these cases of mistaken diagnosis, for years past at least, all have manifested symptoms of a failure of mental integrity, and not a single one has been found to be a victim of malicious persecution or of improper motives.

And so it is of the utmost importance that the members of this society, together with the great body of medical men whose opinions, unfortunately, were not sought by the eminent legislators who were engaged in the revision of the law, should carefully study its provisions and method of procedure; to the end, on the one hand, that they may make its application as harmonious as possible, and, on the other, that they may exert their influence in procuring the correction of such faults as may be found to exist. And furthermore, if it is found that, with the most judicious management, a strict method of procedure under the present law is likely to prove prejudicial to the interests of the insane, there can be little doubt that the judges will be able and willing so to interpret its provisions as to remove or greatly mitigate any asperities that may be discovered, in case the defects in the law are properly brought to their knowledge.

The character of the law, as a whole, can be most conveniently studied by considering each of its provisions by itself.

The first provision, in logical order regarding the certification of the insane, is the petition. This is a form under which some person is required to take the initial step of requesting that an alleged insane person be placed under legal care; and in this petition the petitioner must state some reason why he thinks the cer-

tification should be made. Now this is a step that has always been taken, and that always must be taken in some way. Some person who is interested always does make a request, either to an officer of the State, or more likely to a physician, that the alleged lunatic be examined with reference to his mental condition. He makes this request or petition because he has reasons for making it; and any physician he might consult would certainly ask for and receive a statement of these reasons. The only difference, then, between what was done under the former law, in this respect, and what is required under the new, is the putting of the request or petition in legal form, and so making it a matter of record, in like manner as the certificate of the examining physicians is made a matter of record. In the revision of the law the legislators have probably had in mind the precedent furnished by the lunacy laws of England and of Scotland, in accordance with which a petition, made in due legal form, is the first step in the process of certification. Or, they may simply have thought that a request or petition was logically a step that should be made part of the record.

The question now is, whether this placing of the request or petition in legal form and making it part of the record is open to objections; and, if so, what the objections are, and how they may best be obviated.

It is clear that the petition can not increase the responsibility of the physicians. On the contrary, it must diminish their liability to suffer from suits for damages. But it is possible and even probable that, in some cases, the necessity of making a formal petition may deter friends of insane patients from seeking to place them under legal care as soon as they otherwise would do, so that great damage may thus be done to some of the insane by diminishing the probabilities of a cure. Ordinary delays are often prejudicial. Additional delays would serve to increase the danger. It may be said that invalids should not be allowed to suffer through a mere technicality or sentimentality. But things must be taken as they are, rather than as they ought to be.

The petition is liable to be a deterrent in three different ways: First, through an unwillingness to take the formal initiative; in the second place, through lack of knowledge how to make the petition in proper form; and, in the third place, through an unwillingness to seek the services of a lawyer in a case which seems to the petitioner, at least at this stage, as being purely medical in its nature.

The first of these possible deterrents can not be entirely avoided while the law remains as it is. But its force may be greatly diminished, if not entirely obviated, by showing that the petitioner always has and always must take the initiative; that it is a responsibility that he ought to take; and that the jurat does not really increase his responsibility.

The second and third of these deterrents may be

easily and entirely obviated by the medical examiners. When the petitioner calls in the services of the examiners, as he always must do, and when he has stated to them his reasons for seeking their services, they have only to write his statements in the petition in proper form, with a request that he have the jurat added by the most convenient notary. This will add little if at all to the labors of the examiners; for, in any case, they would keep a record of the pertinent statements of the petitioner. But, in addition, the examiners might arrange to have the jurat of the petitioner taken at the same time with their own, either at their office or at some convenient place elsewhere, thus relieving the petitioner of the annoyance even of seeking the services of a notary.

The suggestion has been made by the State Commission in Lunacy that "medical examiners are required to fill out only the certificate." But, while they are required to do this only, the statements above made may serve to show how physicians may remove obstacles which might seem serious to friends of patients with little trouble to themselves.

The next point for consideration is the personal service. The law directs as follows, to wit: "Notice of such application (or petition) shall be served personally, at least one day before such application, upon the person alleged to be insane," etc. The object of this provision was, undoubtedly, the prevention of the confinement of persons who were not insane, as lunatics, under the hypothesis that hitherto this has been an imminent danger. It may safely be assumed that medical men who are conversant with the subject will agree in the opinion that it was not needed; but the point that now requires especially to be considered is, whether it is likely to be prejudicial; and the answer to this question will depend very much on the interpretation that may be given to the provision, and on the disposition of the judges in regard thereto.

If the personal service regulation is interpreted to mean that a formal legal paper is to be served, informing the mental invalid that an application is about to be made to the court to have him declared a lunatic, and that he is to be placed in legal custody as such, the service of such a paper can be considered little less than an outrage. It would be a sort of citation to answer a legal charge of being a lunatic, and offensive as such. But certain lawyers, at least, have so interpreted the intent of the law. If this is the proper interpretation, medical men who are conversant with the subject can hardly fail to agree in the opinion that judges should, in almost every case, dispense with the personal service, on the ground either that the service would be injurious, or that it would be useless, because the patient would fail to understand its meaning. The mere pretense of serving such a paper, without the person served having an opportunity or the ability to get a knowledge of its contents, would be worse than an

evasion or a subterfuge—it would be a fraud. And it may be asserted with little fear of contradiction that very few lawyers or judges would be willing to serve such a paper on an intimate friend or on a member of their own family. It may be admitted, however, that in very rare cases indeed the service of such a legal paper, or even the formal trial of an alleged lunatic before a judge, may be of advantage to the patient. This would happen especially in incurable cases, which are sometimes classed as paranoiacs. But the same course might have been pursued under the former law.

If, however, personal service is interpreted to mean a verbal statement to the supposed lunatic that, in accordance with the advice of eminent physicians, measures were being taken to have him placed under medical custody and treatment at a specified place, or some equivalent statement, the personal service provision may not only be made harmless, but even advantageous, with the proviso that it be dispensed with in unsuitable cases.

It is probably not well enough understood that in the case of many of the insane a candid statement should be made to them of what is proposed to be done; that under the best medical advice it has been decided to place them in some specified hospital or under some specified care. This course tends to prevent a feeling that they have been unfairly dealt with, or that they have been deceived, and so renders them better satisfied with the care under which they may be placed. Otherwise they are apt to think that some mistake has been made, that they are unjustly and illegally detained; and so the moral influences that may be brought to bear upon them at the hospital may for a time be rendered nugatory.

But there are reasons in many cases why it is better to delay informing the patient of what is being done until his arrival at the hospital; to which he may often be taken without protest and without any explanation whatever. In the first place, the friends of patients may be so averse to having them informed of what is being done that they would neglect or refuse to seek such care and treatment as may be urgently needed. They may have fears lest the invalid should be excited and so injured by the information, or lest he should make a violent opposition which would be very distressing to other members of the family. And, in fact, these fears would often be realized. But many patients who would strenuously oppose removal to a hospital, if informed of it in advance, quietly accept the situation when they are once there, and are then informed of what is being done for them, as should always be the case when the patient has intelligence enough to appreciate what is being said.

A wise provision is made under the revised lunacy law whereby the judge may, in his discretion, dispense with personal service, by making a formal statement of his reasons therefor.

If, now, personal service be interpreted to mean the placing in the hands of the alleged lunatic of a legal paper informing him of the charge about to be made against him, there is likely to be little difference of opinion among competent alienists that the personal service should be dispensed with in almost all cases.

When personal service, however, whether formal or verbal, is dispensed with, the judge will naturally depend upon the medical examiners for the reasons on which his decision is founded. If a statement of these reasons by the medical examiners in the certificate should be considered satisfactory by the judges, as would seem probable, this method would have the merit of simplicity; and, moreover, the reasons of the medical examiners would constitute a part of the record in the body of the certificate.

Whenever personal service has been made, whether formal or verbal, it would seem that a statement of the fact in the petition should be a sufficient verification for the information of the judge. This procedure, moreover, would have the merit of simplicity, and of constituting a part of the record.

The procedure for the certificate of the medical examiners remains the same under the revised law as under the old, and hence does not require examination.

The order of hearing under the revised law does not differ essentially from the legal measures that might have been and sometimes were instituted, *de lunatico inquirendo*, under the old law, and so does not require consideration.

In regard to the functions of the judge, the revised law differs from the old in this, that now "the judge to whom such application is made may, if no demand is made for a hearing in behalf of the alleged insane person, proceed forthwith to determine the question of insanity, and if satisfied that the alleged insane person is insane, may immediately issue an order for the commitment of such person to an institution for the custody and treatment of the insane"; while the old law directed that "no person shall be committed to or confined as a patient in any asylum . . . except upon the certificate of two physicians, under oath, setting forth the insanity of such person"; and that "such certificate be approved by a judge or justice of a court of record." The discussion of the five-day clause is deferred until later on.

Now, whether the functions of the judge, under the revised law, are likely to increase the difficulties and cause harmful delays to be experienced in the process of placing mental invalids under needed care and treatment will depend in part on the interpretation given to the law, and in part on whether the judges are disposed to view the welfare of thousands of insane patients as of paramount importance, or whether they believe it to be the most important part of their duty to prevent the possible mistake of having a person who is technically sane adjudged a lunatic; an event which

is liable to happen under any possible method of procedure; for it will readily be understood that such mistakes could only be made in cases in which the person had acted more or less like a lunatic. And it is proper to state in this connection that none of the commissioners in lunacy of this State have ever found a case in which a sane person was declared a lunatic through improper motives.

The distinguishing point of difference between the wording of the new law and the old regarding the functions of the judge is that under the former he "may proceed forthwith to determine the question of insanity, and if satisfied that the alleged insane person is insane may immediately issue an order for the commitment of such person," while under the old law the judge approved the findings of the medical examiners; and this approval constituted the authorization for placing the insane person in hospital care.

It was certainly the intent of the old law that the judge should be satisfied of the insanity of the alleged lunatic. It was to this end that the evidences of insanity were written out in the medical certificate; and it was to this end that certain physicians were qualified as medical examiners, thus indorsing them as witnesses upon whose testimony and opinions the judges might rely. And this approval of the judge certainly had the effect of an orderly commitment. But it was not intended that the functions of the judge should of necessity be a trial of the case, although he had the power to "institute inquiry and take proofs as to any alleged lunacy before approving or disapproving of such certificate." And he might, "in his discretion, call a jury in each case to determine the question of lunacy." So far as appears, then, from the wording of the law, there is no substantial difference between the old and the new, in regard to the functions of the judges. And so it is quite within the sphere of their duty to make the procedure in lunacy cases quite as prompt and as little obstructive under the new law as it was under the old. Nor is there any sufficient reason to believe that the increase of formalities under the new law will induce judges to place obstructions where none, of necessity, exist; and especially when it is brought to their notice that obstructive delays are sure to be injurious.

If, then, the procedure for the commitment of insane persons to hospital or other care, under the revised lunacy law, can be put in practice in some such simple way as has been suggested, to wit, by the examining physicians undertaking the management of whatever pertains to the petition by including in the petition the statement that personal service has been made, if this has been the case; or by including in the medical certificate a statement of the reasons why personal service is considered unadvisable, if this is the case; and with the wise concurrence of the judges in avoiding such formal obstructions as are required neither by the terms of the law nor by the nature of the particular case in

question; there seems to be no reason why the procedure need be obstructive in its character, in so far as the actual provisions of the law are concerned.

But a provision of the old law which was very important in character has been omitted in the new—the five-day clause, under which a person who had been found by legal medical examiners to be deranged in mind might be placed and detained in a hospital for the insane for the term of five days before securing the approval of a judge. This provision was included in the law of 1874 at the suggestion of the Medical Superintendent of the New York City Hospital for the Insane, with the explanation that patients were sometimes received at the hospital in such a state of physical exhaustion that recovery was hopeless, but some of whom, at least, might have been expected to recover if they could have received proper care a little sooner. In some of these cases the attack had been sudden and severe, or had supervened during an attack of some other exhaustive disease; or, in other cases, friends had delayed placing them under proper treatment until exhaustion was imminent. The time required to find a judge and for legal formalities was sufficient to decide the question between recovery or death. And at that time the legal formalities were few. The necessity for some such provision was still greater in the country, where both hospitals and judges were often difficult of access. It was found also that this provision, which was intended for emergencies only, was of great use under less serious circumstances; as when the insane person was dangerously violent, or suicidal, or so noisy as greatly to disturb the neighborhood; or when he had no home or no friends to undertake his care. The five-day clause simply provided for legal, humane detention in a hospital, where proper treatment as well as care could be furnished; instead of detention without the authority of law at home, in a hotel, in a police station, or in some other place unsuited to the requirements of the case.

It should be stated, however, in this connection, that the five-day clause of the former lunacy law, which was intended by its originators for cases of emergency only, was not so understood by many physicians. They understood and made use of it as subserving purposes of mere convenience. Indeed, the practitioners of a neighboring city perverted its intent by uniformly neglecting to secure the approval of a judge at all, leaving it for the physician in whose care the patient had been placed to secure such approval. In the re-enactment of the emergency clause, then, it should be clearly stated that it is a provision for cases of emergency. The examining physicians should be required to state in the emergency certificate what the emergency is; and a copy of this certificate should be submitted to the judge when he is called upon to act in the case.

A little more than a year ago, when certain lawyers were urging the enactment of laws which should pre-

vent the kidnapping of sane persons and confining them as lunatics, or, at least, the prevention of mistakes in diagnosis, and who among other measures of prevention were urging the abrogation of the emergency clause, a circular letter was written to the medical superintendents of the hospitals for the insane of this State making inquiry whether they considered this provision as a useful one. Ten replies were received, and all of these replies were in the affirmative, and to the effect that the emergency clause should be retained as a part of the lunacy law. When physicians in general practice express this opinion, as they generally if not uniformly do, it may be alleged that they are interested in having the power to rid themselves of a particularly trying patient. But it can not be maintained by the most censorious that hospital superintendents are influenced by any such motives. The motives which impelled them to this opinion were evidently unselfish and humanely in the interest of the patients who came under their care; for the reception of patients under the emergency clause was a source of anxiety, lest the examiners should fail to secure the required approval in due time.

But the view that the emergency clause is a useful one is not confined to the physicians and the medical superintendents in the State of New York. This provision has been included in the lunacy law of England, enacted in 1890, and also in the lunacy law of Scotland. The English law is, in part, as follows, to wit: "In cases of emergency where it is expedient, either for the welfare of the person (not a pauper) alleged to be a lunatic, or for the public safety, that the alleged lunatic should be placed forthwith under care and treatment, he may be received and detained at an institution for lunatics, or as a single patient, upon an urgency order, made (if possible) by the husband or wife or by a relative of the alleged lunatic, accompanied by one medical certificate." Also, "an urgency order shall remain in force for seven days from its date."

The Scotch emergency provision is similar in character, but allows detention for three days only, without the usual legal order.

Inasmuch as the practice in this State for more than twenty years, the unanimous opinion of general practitioners, of examiners in lunacy, of State commissioners in lunacy, and of superintendents of hospitals for the insane of this State, and the practice both in England and in Scotland are in favor of a law authorizing the detention of alleged lunatics, in emergencies, for a certain period of time, it is incumbent on those physicians who are especially interested in the welfare of the insane to unite in urging upon the Legislature the re-enactment of the emergency clause of the lunacy law, with such modifications as may serve to prevent its abuse and give it definiteness of form.

And then, if the expectation is well founded that the judges of the State of New York will be disposed

so to interpret the provisions of the revised lunacy law that the mode of procedure shall be as fully in the interest of those unfortunate persons who are to become the wards of the State as was the mode of procedure under the former law, there can be little doubt that physicians will be able and willing so to act, direct, and manage as to protect their patients from harm and relieve the friends of their patients from undue anxiety and annoyance.

## Therapeutical Notes.

**The Abortive Treatment of Coryza.**—M. Lermoyez (*Thérapeutique des fosses nasales; Journal des praticiens*, October 17, 1896) recommends the following mixture, which is a simplification of Brand's:

R Pure carbolic acid,	{ each . . . . .	75 grains;
Ammonia water,		
Alcohol . . . . .	150	"
Distilled water . . . . .	225	"

M. S.: Ten drops to be poured on to blotting paper, and the vapor inhaled by the nose for a few seconds, every two hours.

Among the abortive snuffs, says the author, the following is excellent:

R Cocaine hydrochloride . . . . .	7½ grains;
Menthol . . . . .	4½ "
Salol . . . . .	75 "
Boric acid . . . . .	225 "

M. S.: A large pinch to be used every hour.

**Erodium Cicutarium as a Remedy for Uterine Hæmorrhage.**—According to the *Journal des praticiens* for October 31st, Komoroviez has employed an infusion of this geraniaceous plant (made from one part of the plant and twelve parts of distilled water) in the treatment of puerperal metrorrhagia and hæmorrhage due to uterine fibroids, and found it even more powerful than ergot. He gives the infusion in doses of a dessert-spoonful every two hours.

**The Local Treatment of Diphtheria with Sodium Hypsulphite** is recommended by H. A. Wickers (*Lancet*, June 6, 1896; *Centralblatt für innere Medizin*, October 31, 1896) as an adjunct to the general treatment. He employs a saturated solution, mixed with an equal amount of glycerin, to be applied to the diseased parts once or twice a day.

**Morphine, Atropine, and Chloral as Corrigents of Chloroform and Ether.**—Dr. E. Fraenkel (*Tagesfragen der operativen Gynäkologie*, 1896, vi; *Centralblatt für Chirurgie*, November 7, 1896) recommends the following formula:

R Morphine hydrochloride . . . . .	2 grains;
Atropine sulphate . . . . .	0.2 grain;
Chloral hydrate . . . . .	3.5 grains;
Distilled water . . . . .	210 "

M. From one to one and a quarter cubic centimetre to be given subcutaneously before beginning the anæsthetization. The author states that he has used this corrigent solution in thousands of gynaecological and obstetrical operations, without a single death or serious case of asphyxia due to chloroform and almost without any unpleasant effects of the anæsthetic.

## THE NEW YORK MEDICAL JOURNAL, A Weekly Review of Medicine.

Published by  
D. APPLETON & Co.

Edited by  
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, NOVEMBER 28, 1896.

### THYREOIODININ.

In the *Münchener medicinische Wochenschrift*, 1896, No. 14, there are three articles on thyreiodinin—the first by its discoverer, Dr. E. Baumann, the second by Dr. E. Grawitz, and the third by Dr. A. Hennig. Abstracts of all of them are given in the *Centralblatt für innere Medizin* for September 19th. Baumann describes thyreiodinin as containing nitrogen and iodine in very stable combination and as being almost insoluble in cold water and in ether. It gives off no iodine hydride on being boiled with dilute acids. In this respect it has a remarkable resemblance to an iodine compound recently prepared by Drechsel from corals. Only a small amount of free thyreiodinin is contained in the thyroid gland, most of it being combined with albumin and globulin, but by repeated extraction with diluted chloride-of-sodium solution all the iodine compounds may be removed from well-minced glands. Since an effect is often seen earlier from thyreiodinin than from the fresh gland, it may be assumed that thyreiodinin is the active principle of the gland.

A curious thing mentioned by Baumann is the fact that numerous observations show that in Hamburg and Berlin the thyroid gland contains much more iodine than in Freiburg, as a rule, and that this is particularly the case with children, in whom the amount is relatively small. The quantity of iodine contained in the gland seems to be but little influenced by disease, but to be notably increased if iodine in any form is absorbed. Since only a very small amount of iodine is found in goitres, and since the amount found in the gland in goitrous regions is small, it seems probable, says Baumann, that the old doctrine of the influence of the quantity of iodine present in a locality—in the food, in the air, and in the water—on the development of goitre receives fresh support. Iodine is an element necessary to life, and if no marine fish are consumed, it must enter the system chiefly in the vegetable food.

Baumann has recently succeeded in finding iodine in the thymus of the calf, and he thinks it probable that in that organ also it exists in the form of thyreiodinin. In most instances, when the amount of thyreiodinin contained in the thyroid gland has once

been increased by the ingestion of iodine into the system it remains abnormally large for a long time. Ordinarily, therefore, a good deal of thyreiodinin is found in the thyroids of persons who have taken iodine for a time. This is true even of goitrous individuals, although usually the amount of iodine contained in a goitre is smaller than that contained in the healthy gland.

Grawitz's article is on the action of thyreiodinin on metabolism in obesity. Both he and Hennig have found it prompt and decided. Hennig's results with the remedy in goitre have not been constant, and he has observed no effect from it in exophthalmic goitre, but, on the other hand, certain affections of the skin and of the sexual organs have seemed to him to lie within the range of action of thyreiodinin. Among the untoward effects he mentions headache, attacks of dizziness, palpitation of the heart, tremor, increased frequency of the pulse, and temporary albuminuria and glycosuria.

#### SOME OF THE DIFFICULTIES OF CATHETERISM IN THE MALE.

DR. A. KOLLMANN has contributed an article on this subject to a *Festschrift für Benno Schmidt* recently published in Leipsic. An abstract of the article appears in the *Centralblatt für Chirurgie* for October 10th. The author deals with the hindrances to catheterism under normal conditions of the urethra, with no impediment in the way of urination. He refers them to the pubic symphysis, the middle layer of the perineal fascia, the sinus of the bulb, the prostatic sinus with the prostatic ring, and the trigonum vesicæ of Lieutaud, the most important of which, he says, is the sinus of the bulb. Among the circumstances which may lead to difficulty at this point is unusual sensitiveness of the mucous membrane of the part, contact of the catheter with which gives rise to spasmodic constriction of the membranous portion of the urethra, constituting the spastic stricture of authors. A point of greater significance is the amplitude of the bulbous portion of the urethra with an abundance of folds; and another is an unusual distance between the sinus of the bulb and the entrance to the isthmus.

As regards the folds and pockets of the remainder of the anterior urethra, the author agrees with Dittel and Grünfeld that importance is to be attributed only to the pocket on the upper wall of the fossa navicularis, often connected with a Morgagnian lacuna, and to the little rhaps of mucous membrane on the border of the Morgagnian crypts of the pars cavernosa. Occasionally the former is remarkably deep, so that the instru-

ment may catch in it; the latter can hardly prove a hindrance unless a fine flexible instrument is used. The same is true of the excretory ducts of the acinous mucous glands. In the normal condition of the urethra they are minute depressions invisible to the naked eye; under the influence of gonorrhœa, however, they may attain to a notable size, but never to a size sufficient for them to constitute an obstacle to the introduction of a rigid instrument. It has been in urethroscopy, says the author, and especially by the observations of Oberländer, Neelsen, and Finger, that the relations of the mucous glands of the urethra and the pockets and hollows partly connected with them have been made clear within the last few years.

Folds, pockets, and hollows of other sorts capable of hindering catheterism the author regards as very exceptional. He cites a case of Grünfeld's in which there was an opening in the posterior wall of the urethra, situated about three inches from the external meatus, that led to a submucous passage an inch deep into which an instrument as large as that numbered 15 on Charrière's scale could be inserted. He adds that a like instance has come under his own observation. On the lower wall of the urethra, in front of the bulb, there was a blind passage about half an inch deep, lined with urethral mucous membrane and opening anteriorly, which ran parallel with the urethra and readily admitted a No. 23 catheter. He thinks that such diverticula are not to be looked upon as acquired, but as congenital.

In one instance Dr. Kollmann has had the opportunity of observing a rudimentary pocket formation capable of constituting an impediment to catheterism, and of a kind that he has not found mentioned in endoscopic literature. This, too, he regards as a congenital formation corresponding in situation to the outlets of Cooper's glands, and the remark is made that in many dissections Henle saw the excretory ducts of these glands marked by little folds and pits. The author suggests that an examination with the urethroscope should not be begun at the bulb and carried forward toward the glans, but *vice versa*, to avoid overlooking certain pockets in consequence of closure of their entrances. He himself uses a special tube of his own contriving the free end of which is bent obtusely so that injuries may be avoided.

#### MINOR PARAGRAPHS.

THE ORTHOPÆDIC SECTION OF THE NEW YORK ACADEMY OF MEDICINE.

ON Friday evening, November 20th, Dr. James K. Young, of Philadelphia, read an important and valuable

paper On the Treatment of Lateral Curvature of the Spine by Light Gymnastics before this section. The discussion was participated in by Dr. E. H. Bradford, Dr. Augustus Thorndike, and Dr. John Dane, of Boston; Dr. De Forest Willard and Dr. H. Augustus Wilson, of Philadelphia; Dr. R. Tunstall Taylor, of Baltimore; and Dr. L. A. Sayre, Dr. J. D. Bryant, Dr. V. P. Gibney, Dr. J. Terchner, Dr. H. L. Taylor, Dr. S. Ketch, Dr. T. H. Myers, Dr. W. R. Townsend, Dr. L. W. Hubbard, Dr. H. W. Berg, Dr. R. H. Sayre, Dr. R. Whitman, Dr. A. B. Judson, and the chairman. Prior to the meeting the chairman of the section entertained the above-named gentlemen at dinner at the University Club. Others who had been invited were unable to attend. Among them were Dr. John Ridlon and Dr. F. S. Coolidge, of Chicago; Dr. A. J. Steele, of St. Louis; Dr. A. J. Gillette, of Minneapolis; and Dr. Roswell Park, of Buffalo.

## ITEMS.

### The New Vaccine Virus in Liquid Form prepared in the Laboratories of the New York Health Department.

Early in 1895 the vaccine laboratory of the health department was attached to the Division of Pathology and Bacteriology, and a detailed experimental investigation into all the methods employed in various parts of the world for the production and preservation of vaccine virus was immediately begun and has been continued to the present time. The choice and care of animals, the places, methods, and virus most suitable for inoculation into the animals, the time and manner of collection, and the preparation and preservation of virus after collection have all been subjects of study. In addition, the most notable vaccine laboratories in Europe and this country have been visited and their practice has been studied.

In consequence of the investigations, numerous modifications in the methods have been made, but the most important is the entire change in the form of the vaccine virus issued and recommended for use. Formerly the virus employed was the serum which issued from the base of a vaccine pock, dried on quills or ivory points. To determine the most valuable part of a vaccine vesicle, the following experiment was made: A typical vesicle was chosen and the crust, the underlying pulp and base, and the serum exuding after the former were removed, were collected separately. Each was mixed with glycerin in the proportion of sixty per cent. of vaccine matter and forty per cent. of glycerin, then thoroughly comminuted in a mortar, and the products were used in the multiple vaccination of children. The pulp showed by far the best, the crust the next, and the serum the poorest results, as determined by the percentage of successful vaccinations. Other similar experiments confirmed these results, and it was concluded that the largest proportion of the active virus was contained in the pulp. Therefore the virus now issued is in the form of a glycerinated vaccine pulp. The function of the glycerin is to produce a homogeneous mixture and to act as a safe antiseptic against germs accidentally introduced.

Although led by its own observations to adopt the liquid form of virus, the health department, in supplying such vaccine, is only following the example of all the best German, French, and other Continental vaccine laboratories, and it is believed that no other virus is more fully tested before being issued than that prepared in the laboratory of the New York city health department. The greatest care is taken to insure cleanliness in the production and preservation of the virus; all instruments and receptacles are sterilized and the operations of inoculation and collection made as nearly aseptic as possible.

Before using the virus derived from an animal, first, the animal from which it was obtained is sent to autopsy and the organs are examined for any evidences of disease; second, two samples of the virus are given, one to the bacteriologist, and the other to the medical tester of virus, and

no virus is issued unless the reports of the pathologist, bacteriologist, and clinical tester are all satisfactory. The clinical test consists in the inoculation of the virus after scarification in three places on each of five children who have never previously been vaccinated. There is thus a case test of five and an insertion test of fifteen points. The results from the new method with this rigid system of tests are shown in the records of the last three months. Since July 1, 1896, there have been vaccinated in the routine way thirty calves from which virus has been collected and tested as above described. All this virus gave one hundred per cent. case and one hundred per cent. insertion success at the original test, and the same percentages of success at the last retest made about October 1, 1896. There can therefore be no doubt that the durability of the virus is assured for at least three months from the date of collection.

Worthy of note is the fact that in all the primary vaccinations made during September and October by the department vaccinators, in which the results are known, more than seven hundred in number, there was not a single failure.

The virus is a syrupy, opaque, brown emulsion of uniform consistence. It is put up in convenient capillary tubes containing each enough for a single vaccination and in phials of two sizes, one containing one fifth of a cubic centimetre for ten vaccinations, and the other containing one cubic centimetre for fifty vaccinations.

In using the new virus the skin is scarified in the usual way, and a drop of the liquid virus (discharged from a capillary tube by blowing out the contents with a rubber tube furnished to facilitate this process) is then thoroughly rubbed into the scarified area with a slip of wood, which accompanies each tube. The new virus, like the other products of the health department laboratories, is furnished free to all public institutions in the city on application. Physicians can obtain the virus at many drug stores, or on application directly to the health department. The retail price of the capillary tubes is ten cents each.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending November 24, 1896:

DISEASES.	Week ending Nov. 17.		Week ending Nov. 24.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	36	6	34	6
Scarlet fever.....	77	6	135	8
Cerebro-spinal meningitis...	1	0	2	2
Measles.....	63	3	81	3
Diphtheria.....	185	28	218	18
Tuberculosis.....	110	84	188	98

**The Twelfth International Medical Congress.**—The chairman of the American national committee of the Twelfth International Medical Congress, which is to meet in Moscow, Russia, from August 19 to August 26, 1897, has issued a circular stating that the committee consists, according to the directions of the general committee in Moscow, of the following gentlemen: J. S. Billings, M. D., New York; Frank P. Foster, M. D., New York; S. Weir Mitchell, M. D., Philadelphia; Charles A. L. Reed, M. D., Cincinnati; George B. Shattuck, M. D., Boston; F. J. Shepherd, M. D., Montreal; George F. Shady, M. D., New York; W. S. Thayer, M. D., Baltimore; and the chairman, A. Jacobi, M. D., No. 110 West Thirty-fourth Street, New York.

The chairman begs to invite the attention of the medical profession of the United States and Canada to the fact that the professional gentlemen in charge of the congress are anxious to make it a success both from a scientific and from a social point of view. Their difficulties are unusually grave; but it is not their fault that the congress had to wait for governmental permission to meet in their country, or that a special ukase was required for the admission into Russia of Jewish medical men on equal terms with their Greek, Catholic, Protestant, Agnostic, and Moham-

medan colleagues; or that the famous and meritorious secretary-general was—it appears because of his liberalism—ousted both from his place and from his professorship. They should not be held responsible for the political semibarbarism of the country in which they live and to whose laws they have to submit. Their position in the world of science and their endeavor to make the twelfth congress equal to its most famous predecessors will prove an incentive to American physicians to sustain, both by their presence and by their contributions, the Russian committee in its exertions to make the next congress equal to its predecessors. Such information as may be received from time to time will be published in the medical journals immediately after its arrival.

**The Richmond Academy of Medicine and Surgery.**—At the last regular meeting, on Tuesday, November 24th, the order for the evening included a discussion on puerperal eclampsia which was to be opened by Dr. J. N. Unshur.

**The Buffalo Academy of Medicine.**—At the last meeting of the Section in Obstetrics and Gynecology, on Tuesday evening, the 24th inst., the following papers were to be read: The *Ætiology and Pathology of the Albuminuria of Pregnancy*, by Dr. A. A. Jones; and *The Treatment of the Albuminuria of Pregnancy*, by Dr. Henry R. Hopkins.

**The Journal of Nervous and Mental Disease.**—The managers announce the following arrangement of the staff for 1897: Editors, Dr. Charles L. Dana, Dr. F. X. Dercum, Dr. Philip Coombs Knapp, Dr. Charles K. Mills, Dr. James J. Putnam, Dr. B. Sachs, and Dr. M. Allen Starr; associate editors, Dr. Philip Meirowitz and Dr. William G. Spiller; managing editor, Dr. Charles Henry Brown, No. 25 West Forty-fifth Street, New York, to whom all editorial and business communications should be addressed.

**Anatomy Laws versus Body-snatching** is the title of a valuable article by Dr. Thomas Dwight, Parkman professor of anatomy in Harvard University, published in the December number of the *Forum*. He insists on the need of rational and uniform dissection laws throughout the United States.

**The Royal University of Ireland** has conferred the honorary degree of M. A. O. (master of the obstetric art) on Dr. Thomas Mose Madden, of Dublin.

**The Death of Sir Benjamin Ward Richardson, of London**, is reported to have occurred on Saturday, November 21st, as the result of an attack of apoplexy that had befallen him on the preceding Wednesday. He was sixty-eight years old. He was a most ingenious physician and a voluminous and attractive writer.

**The Death of Dr. Eugen Baumann, of Freiburg**, the distinguished physiological chemist, best known of late for his discovery of thyroiodinin, occurred recently. He was not quite fifty years old.

**Changes of Address.**—Dr. Daniel Lewis and Dr. Charles L. Ogden, to No. 252 Madison Avenue, New York; Dr. A. M. Phelps, to No. 62 East Thirty-fourth Street, New York.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending November 21, 1896:*

ARNOLD, W. F., Passed Assistant Surgeon. Detached from special duty and ordered to the U. S. Steamer Enterprise.  
HIBBETT, C. T., Surgeon. Detached from the U. S. Steamer Independence, ordered home, and granted three months' leave of absence.  
MAGRUDER, A. F., Surgeon. Detached from the Marine Barracks at Washington and placed on the retired list.  
MOORE, J. M., Passed Assistant Surgeon. Detached from the U. S. Steamer Texas, December 7th, and ordered to the U. S. Steamer Castine, December 8th.

OLCOTT, F. W., Passed Assistant Surgeon. Detached from the U. S. Steamer Enterprise and ordered to the U. S. Steamer Independence.

PALMER, S. B., Assistant Surgeon. Detached from the U. S. Steamer Vermont and ordered to the U. S. Steamer Texas.

SAYRE, J. S., Passed Assistant Surgeon. Placed on the retired list. November 16th.

STONE, L. H., Passed Assistant Surgeon. Detached from the U. S. Steamer Castine, ordered home, and placed on waiting orders.

WALTON, T. C., Medical Director. Detached from the Naval Academy, December 15th, and ordered to the Naval Laboratory.

WELLS, H. M., Medical Director. Detached from the Naval Laboratory at New York, ordered home, and placed on waiting orders.

#### Promotions.

CRAIG, T. C., Passed Assistant Surgeon, to Surgeon, from October 14th.

LEACH, P., Passed Assistant Surgeon, to Surgeon, from November 15th.

#### Society Meetings for the Coming Week:

MONDAY, November 30th: Boston Society for Medical Improvement.

TUESDAY, December 1st: New York Neurological Society; New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Herkimer (semiannual)—Herkimer) and Saratoga (Ballston Spa), N. Y.; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Maine, County Medical Association (Leviston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, December 2d: New York Academy of Medicine (Section in Public Health); Harlem Medical Association of the City of New York; Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (Stapleton), N. Y.; Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, December 3d: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Cuyahoga, Ohio, County Medical Society.

FRIDAY, December 4th: Practitioners' Society of New York (private); Baltimore Clinical Society; St. Louis Academy of Medical and Surgical Sciences.

SATURDAY, December 5th: Clinical Society of the New York Post-graduate Medical School and Hospital; Manhattan Medical and Surgical Society, New York (private); West End Medical Society, New York; St. Louis Medical Society; Miller's River, Massachusetts, Medical Society.

#### Births, Marriages, and Deaths.

##### Married.

CAPWELL—BRAYTON.—In Worcester, Rhode Island, on Thursday, November 19th, Dr. Remington Pendleton Capwell, of Slatersville, Rhode Island, and Miss Sarah Paine Brayton.

CLENDENIN—OSGOOD.—In Boston, on Thursday, November 19th, Dr. Paul Clendenin, of the United States Army, and Miss Harriet Brown Osgood.

EMMET—GARLAND.—In New York, on Wednesday, November 25th, Mr. Robert Emmet, son of Dr. Thomas Addis Emmet, and Miss Louise Garland.

**FARRELL—SMITH.**—In Providence, Rhode Island, on Tuesday, November 17th, Dr. John T. Farrell and Miss Louise Allen Smith.

**JOHNSON—STINSON.**—In Canton, Mississippi, on Wednesday, November 18th, Dr. McWillie Johnson, of Kirkwood, Mississippi, and Miss Kate Stinson.

**MACARTHUR—BURDICK.**—In Chicago, on Tuesday, November 24th, Dr. Robert Archibald MacArthur, of Baltimore, and Miss Mary Amelia Prescott Burdick.

**QUIGLEY—GAYNOR.**—In New York, on Wednesday, November 25th, Dr. John J. Quigley and Miss Susan Ruth Gaynor.

#### *Died.*

**GRAHAM.**—In Philadelphia, on Thursday, November 12th, Dr. James Graham, aged fifty years.

**HAYWARD.**—In Cambridge, Maryland, on Tuesday, November 10th, Dr. William Richard Hayward, aged seventy-nine years.

**MERRIGAN.**—In New York, on Saturday, November 21st, Celia Merrigan, wife of Dr. Thomas D. Merrigan.

**PATTERSON.**—In Staunton, Virginia, on Tuesday, November 10th, Dr. Henry M. Patterson, aged sixty-six years.

**POTTER.**—In Rochester, N. Y., on Tuesday, November 17th, Adaline L. Potter, wife of Dr. Darwin Potter.

**RICHARDSON.**—In London, England, on Saturday, November 21st, Sir Benjamin Ward Richardson, M. D., in the sixty-ninth year of his age.

**SASS.**—In New York, on Thursday, November 19th, Dr. Luis F. Sass, in the seventy-seventh year of his age.

### **Proceedings of Societies.**

#### **SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.**

*Meeting of October 14, 1896.*

The President, Dr. R. C. NEWTON, in the Chair.

**Fibroids of the Uterus.**—Dr. BROOKS H. WELLS presented two specimens of uterine fibromata. In the first case the patient had long been vainly treated for sciatica. Finally, beginning to have difficulty in urinating and severe pelvic pain, she had called in another physician, who had found a pelvic and abdominal fibroid, and had sent her to the speaker at the Polyclinic Hospital. Examination had shown an immovable tumor extending from the umbilicus to the perineum, and closely filling the pelvic cavity. Tumor and uterus had been removed by abdominal hysterectomy. The adhesions had been numerous and dense. The bladder had extended over the front of the tumor to the umbilicus and had been accidentally opened in making the abdominal incision. The rent had been immediately sutured, and had given no further trouble. Recovery had been uneventful.

The second specimen had been removed post mortem by Dr. Newton, of Montclair, N. J., from a patient dead from cardiac disease. It had caused no symptoms during life. It was an interstitial fibroid with numerous pedunculated subperitoneal nodules.

**Intestinal Resection.**—Dr. WELLS also presented a portion of gangrenous intestine removed from a boy, ten years of age, who had had severe colic and vomiting after gorging himself with raw green corn, cucumbers, and overripe bananas. After the stomach had been emptied he had been given a dose of castor oil, and directions had been left to call the doctor the next day if all was not right. Thirty hours later the speaker had been

sent for, as the boy's bowels had not moved, and he had found the child in collapse with marked symptoms of intestinal obstruction and general peritonitis. He had been sent at once to the Polyclinic Hospital and the abdomen opened. It had contained a large amount of bloody serum. There had been no intussusception or volvulus, but a section of the lower portion of the small intestine had been gangrenous. This had been removed and a circular enterorrhaphy done. The boy had died a few hours later. The section of gut had been found to be twenty-one inches long. Cases of this nature were always desperate.

Dr. GEORGE H. MALLETT thought the pain that accompanied fibroids of the uterus was dependent entirely upon the location of the tumor. Oftentimes the larger ones produced the least symptoms. He spoke of a patient that he had recently seen at the clinic. She had been sent by a physician who had been treating her for disease of the stomach. She had complained of absolutely no pain, but her abdomen had seemed enlarged. Upon examination, a tumor as large as a man's head had been found in the abdomen. The speaker had recently removed a uterus which was little larger than a man's fist. It had been wedged down in the pelvis, and the patient had suffered intensely for a long time.

Dr. ALVAH M. NEWMAN asked if it would not have been easier to remove the fibroid through the vagina.

Dr. WELLS thought not; the fibroid had reached from the perineum to the umbilicus; it would have been almost impossible to reach it from below.

Dr. THEODORE W. CORWIN thought one point of interest was the relation of sciatica to the tumor. He had attended a case of sciatic pain a few months ago, very severe and obstinate, and without associate symptoms to point to any other trouble than the nerve. He had given the patient the usual treatment for neurotic sciatica, and then, as the pain had persisted, had made an examination through the vagina, and had found a retroversion of the uterus with a little lateral flexion. With relief of these by supporting measures, the sciatica had been relieved. Later on, an operation for fixation of the uterus to the round ligaments had been done by Dr. Ill, of Newark, N. J.

Dr. ADOLPH RUPP asked if the sciatica had been cured by the removal of the fibroid.

Dr. WELLS said that four weeks had passed since the operation, and the patient had not complained of it. The only complaint she had made was that she had not been given enough to eat. On the fifth day she had wanted boiled ham and cabbage. She had had no pains since the operation. The tumor had been large enough and the pressure sufficient to cause the sciatica.

Dr. PHILIP ARTHUR MALLESon spoke of a case that he had had some years ago, of a woman about six months and a half pregnant, where the sciatica had been so intense that it had been determined, after exhausting all other methods, to evacuate the contents of the uterus, because it was perceptibly tilted to the side on which she had the sciatica. The uterus had been emptied and the sciatica had disappeared.

The PRESIDENT spoke of a case that he had seen in a man who had had locomotor ataxia. The attending physician had told the family it was an obstinate case of sciatic rheumatism.

**Appendicitis.**—Dr. D. E. WALKER presented a specimen consisting of the vermiform appendix, a piece of omentum, and a concretion which he had removed.

The patient had come to the speaker complaining of pain at the ensiform cartilage and some nausea, without any previous constipation. He had previously been given a dose of castor oil, which he had vomited without change six hours afterward. The speaker had examined him, but had not found, though he had suspected, appendicitis. The abdomen had been somewhat distended, but there had been no tenderness in the region of the appendix. He had sent the patient to bed and had given him some small calomel tablets. The next day the belly had been lax, and he had detected an enlargement of the appendix. The patient had had no pain in that region, but there had been marked tenderness. The speaker had advised an operation, and, pending his decision, had left, with directions to let him know if the patient vomited. The next morning the patient had had agonizing pain in the abdomen, and the temperature had gone up. The temperature before this had not been above 99°. The operation had been at once performed and the appendix taken out, with a concretion at its centre. A small piece of omentum had been attached, forming one side of an abscess which had burst into the peritoneal cavity. There had been general peritonitis. The special point in this case was that the only symptom of pain the man had had had been in the region of the ensiform cartilage, probably caused by the omental involvement. There had been no pain since the operation. He emphasized the fact that whenever a tumor was found the best thing to do was to operate.

The PRESIDENT asked if this was a primary attack.

Dr. WALKER said the man had given a history of several bilious attacks with gaseous distention of the stomach. These had always been controlled with small doses of calomel and had been probably caused by the appendix. The extremity had been rather black-looking, and had appeared almost gangrenous when it was taken out.

Dr. RUPP asked if the symptom of vomiting had decided the question of operation in the case presented. The speaker had treated a case of recurrent appendicitis in which the temperature had been low, the peritonitis general, an evident tremor in the appendicular region, and vomiting intermittently. The patient had recovered without operation, under opium, poulticing, and dieting. He had been advised to consult a surgeon concerning a prophylactic operation, but this he had not done.

Dr. WALKER said that the reason he had given the family directions to send him word if the patient vomited was that usually there was vomiting when the abscess burst, and he knew that it had not burst then. Repeated vomiting, a rapid pulse, and distended abdomen were signs that the tumor had burst, and indicated immediate operation. When the speaker had found that the tumor had burst, he had decided that the only chance was an operation. The patient had had general peritonitis and there had been no other chance of his recovery. Vomiting alone was not always an indication for an operation. The main thing was to find the tumor. The speaker depended more on the character of the pulse than on the temperature, because one often found a very low temperature in these cases.

**Two Fatal Cases of Heart Disease, Unrecognized during Life, with Morbid Specimens.**—The PRESIDENT showed two specimens of diseased hearts that had not been diagnosed in life. The first specimen presented had been taken from a man about fifty years of

age. The man had been apparently in perfect health. He had been quite stout and had objected to walking up hill, as he had suspected that his heart was not all right. He had attended to his business every day. One night, as he was riding home in the railroad train, his head had fallen forward on his breast, and he had died. The family had insisted on an autopsy, of which the record was as follows: "Autopsy made eighteen hours after death. Considerable subcutaneous sufflation. Rigor mortis only moderate. Head not examined. Chest: Muscular tissue interspersed with fat; costal cartilages generally ossified and cut with difficulty; lungs apparently healthy; no pleuritic adhesions except over the left upper lobe anteriorly. Heart very large; pericardium containing six or eight ounces of clear, brownish-yellow serum; inner surface of pericardium somewhat thick and rough (old pericarditis). Heart both hypertrophied and dilated, externally freely covered with fat; muscular substance pale and containing streaks of whitish-appearing substance, which was fibrous tissue from chronic myocarditis; of the right ventricle, the wall was nearly entirely fat, and fat had encroached upon the muscular substance at the apex of the left ventricle. The mitral orifice would admit four fingers of a large hand nearly up to their metacarpophalangeal articulations. There were some patches of atheroma upon the aortic valves and on the inner surface of the lower portion of the arch, also extensive atheroma of the coronary arteries. The heart cavities were empty. There were no blood clots found in the body; in fact, there was very little blood in any part of the body. The spleen was large and soft. Liver not removed; was congested, apparently otherwise normal. Kidneys both removed; great amount of perinephric fat; they were of medium size. Fetal lobulation still present; increased connective tissue. Substance hard and containing here and there small cysts as large as a swan shot. There was chronic interstitial nephritis. Cause of death, heart failure from chronic myocarditis."

The second specimen was that of a diseased heart and uterus taken from a single woman, forty-four years of age, rather spare in habit. She had been a hard-working woman all her life, but had never had any serious illness. Before coming to the hospital she had been feeling miserable for some time, and that morning, on rising, had fainted; when admitted she had been much prostrated; temperature, 98° F.; pulse, 120; respiration, 32. The diagnosis which accompanied her had been neurasthenia. She had died forty-eight hours after admission. At the autopsy, in the heart had been found almost complete obliteration of the mitral orifice. The aortic valves had been entirely calcareous and immovable, and the blood had had to pass through a slit that would scarcely more than admit a knife blade. There had naturally been extreme dilatation of both auricles.

Dr. WALKER spoke of a case that he had seen in the hospital, that had ended fatally a few hours after the patient had been brought in. The autopsy had revealed aneurysm of the wall of the heart. There had been no previous diagnosis of heart disease.

Dr. RUPP asked if the brain had been examined in the cases reported.

The PRESIDENT said they had not been.

Dr. RUPP asked if death had been attributed to the heart.

The PRESIDENT said that it had been.

Dr. RUPP said that one might reasonably differ

from Dr. Newton's opinion concerning the specimens and diagnoses presented. It seemed to the speaker that often, as in these instances, too much importance was attached to heart abnormalities in cases of sudden death. The heart was not an independent organ, however important its functions were as a transmitter of blood between the incoming and outgoing currents. He thought that other causes for the sudden deaths in these cases might have become evident if the search had been allowed to be more thorough, especially in the case of the man who had always been a hard worker, in apparent good health up to the time of his death. Why not in this case think of a sudden cerebral hæmorrhage as well as of heart disease?

The PRESIDENT stated that the family had not wished the brain examined, and he had been satisfied that the condition of the heart had been the cause of death.

Dr. RUPP said he knew a man who had a double mitral murmur, who got along very well, although he was stout. This man was healthy and had been passed as such by several examining physicians for life-insurance societies. It was reported that some London insurance companies were not now so severe in excluding candidates for insurance simply because of an abnormal cardiac murmur. Other conditions on which the well-being of the heart depended were, as they should be, taken into the reckoning: the digestive apparatus, the genito-urinary apparatus, the condition of the blood-vessels and of the lungs. There were some cases of so-called angina pectoris which could not properly be called heart disease any more than one would speak of ear disease when pain was reflected or deflected into an ear from a diseased tooth. In illustration of these remarks, he spoke of a man over sixty years of age who had never had heart trouble or symptoms or signs indicating such, and this man had died suddenly. This man had been overcome by adverse business complications and family worries. Twenty and thirty years before he had had small-pox and yellow fever. He had always been a temperate man. He had died of nervous exhaustion, and the angina pectoris in his case had been but the local explosion of undistributed nervous force. Pathological anatomy and clinical experience did not always coincide.

Dr. HENRY H. SCHROEDER, to illustrate how patients with very serious heart lesions might sometimes live for a considerable length of time, spoke of a case of his that he had examined about three years ago, where there had been a great deal of dilatation and a most erratic heart action, which was very intermittent, irregular, rapid, and weak, so much so that he had told the man's wife he could hardly expect to live three months. Yet the man was still alive in spite of intemperate habits. He had been surprised to hear that the conservative English life-insurance companies were accepting risks with heart murmurs, as the American companies, noted for being more progressive, refused such applicants.

The PRESIDENT spoke of examining a man for insurance who had been told when a boy that he had mitral regurgitation, and the speaker could find nothing the matter with him. In regard to life-insurance companies, he thought no company would, under any circumstances, accept a man who had an organic heart murmur, and inasmuch as it was never quite possible to distinguish organic from functional murmurs, no good life-insurance company would accept a risk with any heart murmur.

Dr. RUPP said he referred to organic and not so-called functional murmur. Organic murmur might exist in a perfectly healthy body. By itself, it might be no evil; in connection with other pathological conditions its presence might be grave.

(To be continued.)

#### MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

*Twenty-second Annual Meeting, held in St. Paul on Tuesday, Wednesday, Thursday, and Friday, September 15, 16, 17, and 18, 1896.*

The President, Dr. HENRY O. WALKER, of Detroit, in the Chair.

(Concluded from page 694.)

**Pleuritic Effusions and their Treatment.**—Dr. GUSTAVE FÜTTERER, of Chicago, thought that a bacteriological examination should be made in all cases, with cover glasses, with culture media, and by injections of the effusion in animals. We must distinguish between exudate and transudate by using the acetic-acid test, and by the same process eliminate mucin. Many cases of pleurisy were due to the uric-acid diathesis. These would yield readily to treatment with the salicylates. He believed that not more than fifteen per cent. of pleuritic patients were rheumatic. The presence of pneumococci did not aggravate the condition, and often gave no very distinct symptoms. Tubercle bacilli were often found in pleuritic effusions. He believed it was not only possible but likely that the tubercle bacilli did penetrate through the alveolar septa, and enter the pleura without producing infection in the lungs. Tuberculosis might be distinguished by the agar culture. Hyperæsthesia of different parts was frequently present.

He had washed out the cavity in fourteen cases with an antiseptic solution of from one half to two per cent. of clove oil, with most gratifying results in twelve of the cases. The advantages of this method were: Many patients would allow such an operation who would object to excision of a rib; there were no bulky dressings constantly interfering with the comfort and convenience of both patient and physician; and a much shorter time was required.

**Nerve Suture and other Operations for Injuries to the Nerves of the Upper Extremity.**—Dr. A. J. OCHSNER, of Chicago, said that his own observations and a study of the literature on this subject had led him to the following conclusions: 1. every severed nerve should be sutured, even after a number of years. 2. The earlier the operation was performed the better. 3. If neither sensation nor motion was established within a year, the nerve should be exposed anew, the cicatricial tissue removed, and the ends again sutured. 4. The end should be clean cut and should contain neither crushed nor cicatricial tissue. 5. Tension must be avoided. 6. The wound must heal without suppuration to secure the best results. 7. Hæmorrhage should be perfectly controlled to prevent an intervening clot. 8. Carefully prepared catgut was the best suture material. 9. After suturing of the ends, either directly or at a distance, it was well to stitch a fold of fascia over them. 10. The limb should be placed at rest. 11. The external incision should be ample.

**Woman and her Diseases versus Gynæcology.**—Dr. HENRY P. NEWMAN, of Chicago, thought that we were

coming to a period of transition in the practice of surgical gynaecology; instead of essays on the treatment, we now had studies on the cure and prevention. Preventive medicine, hygiene, sanitation, and sociology were now popular themes for medical societies. Philanthropy had taken the cue from medicine, and was attempting to form a citizen rather than reform him. He emphasized the fact that we were not dealing with the "cold-science" side of our art, but with the highest of human interests. The amount of ignorance of Nature's requirements shown by the average woman was appalling. Woman's sphere had lately widened until now it was as wide as man's. Had she equipped herself for this race intelligently? Look at the average women in the cities—the stenographer, the saleswoman, the business woman—did they not daily outrage their bodies by compliance with the dictates of fashion in food, dress, and habits? The tendency of gynaecologists to enter surgery was to be deprecated. It narrowed their opportunities. They had better stay attached to obstetrics and pædiatrics. A woman's generative organs should not be doomed because she needed to visit the gynaecologist. A good diagnostician must know as much about women as about disease, as much about environment and social and domestic relations as about pelvic lesions. As specialists, we must recognize the medical science which would prevent rather than cure disease. As we knew that what could be acquired might be prevented, we as specialists should lead in the reform of those conditions which were detrimental to the health of women.

**The Pathology and Treatment of Suppurative Salpingitis.**—This was the title of a paper by Dr. F. F. LAWRENCE, who remarked that the tubal mucosa was a true mucous membrane, possessed of all the histological elements of mucous membrane. The fimbriæ were prolongations of the folds of mucous membrane, with a few muscular fibres beyond the end of the tube.

The closure of the end of the tube was effected by, first, the unfolding of these plicæ and the elongation of the muscular fibres, with coincident inflammatory exudate, and not by adhesions of the peritoneal surface; second, the formation of adhesions between the fimbriæ and other structures; third, imbedding of the fimbriæ in inflammatory exudate. Closure of the tubal ostia resulted in the formation of circumscribed abscess. Occasionally the uterine end of the tube remained patent, when the abscess in the tube communicated with the uterine cavity, through which it might in part discharge its contents. The treatment of suppurating tubes could not be fixed by any rigid rule. Each case must be treated according to the conditions it presented. We must incise and drain in some cases. Seldom would vaginal section be required, and only in carefully selected cases. Hysterectomy was indicated in cases where we found abscess of the uterine wall, tuberculous deposits, fibroids, or malignant disease in the fundus. Hysterectomy should never be performed except where there was some tangible lesion of the uterus. Abdominal section would be necessary in many cases.

**The Importance of Physical Signs other than Murmurs in the Diagnosis of Valvular Disease of the Heart.**

—Dr. JAMES B. HERRICK, of Chicago, said that standard text-books taught that an endocardial murmur was not always an evidence of a valvular lesion, and also that a valvular defect might exist and still no murmur be present. Practically, however, conclusions were usu-

ally based upon the presence or absence of a murmur. This was wrong, for there might be valvular disease without a distinct murmur being audible. Other signs than a murmur must be used in determining the existence of a valvular lesion. Every valvular lesion must result in hypertrophy and dilatation of the heart behind the valve diseased. An increase in tension of the pulmonary circulation followed any valvular lesion at the mitral orifice, and later any aortic disease. This would show in increased force of the pulmonic second sound. Stenosis of the left orifices of the heart meant a smaller amount of blood in the general arterial circulation, therefore lessened arterial tension. Failure of the right heart was followed by venous congestion, causing a venous pulse, hepatic and portal congestion, anasarca, etc. Hypertrophy might be recognized by the heaving, forcible apex impulse. Epigastric pulsation might call attention to enlargement of the right heart. The jugular, the hepatic, and the capillary pulse were all of diagnostic value. The visible pulse of aortic regurgitation was almost pathognomonic. Palpation was important. Extracardiac causes of a murmur, such as might arise in a heart displaced by pressure or retraction, could usually be excluded by percussion. A weak aortic sound might be an indication of obstruction. The reduplicated second sound might point to valvular disease. A sharply accentuated first sound at the apex was common in mitral stenosis. The peripheral tones in aortic regurgitation were a valuable confirmation. The error of calling an inorganic murmur organic was readily made, unless the secondary sounds were carefully sought for. Dr. Herrick did not undervalue the importance of endocardial murmurs, but insisted that it was only by the complexus of signs and symptoms that an accurate diagnosis could be made. Of all the evidences of heart disease, the least valuable was the endocardial murmur.

**The Value of Secondary Physical Signs in the Diagnosis of Cardiac Diseases.**—This was the subject of a paper by Dr. R. H. BABCOCK, of Chicago. Murmurs were the least reliable signs of valvular disease. An accurate diagnosis could not be made unless the secondary signs of valvular disease were recognized. If the heart's action was not sufficiently strong there might not be any murmur, or a grave defect might not be observed for the same reasons. Secondary symptoms were modified pulse rate, character, and rhythm, leading to congestion of the veins and internal organs. In some instances there was also systolic venous pulsation of the liver. Systolic jugular pulsation was diagnostic of insufficiency, even if a murmur was not audible.

**Water.**—Dr. I. N. LOVE, of St. Louis, read a paper thus entitled. Drugs, he said, seemed to be the chief inspiration in the life work of too many men. Hydropathy had been of wonderful service to humanity. We could appreciate the necessity of water when we remembered that seventy-five per cent. of the body was made up of water. It was just as important as the solids in life's conditions. The demands for water were affected by the amount of muscular exercise and the degree of temperature to which the body was exposed. For an irritated stomach or bilious colic nothing was superior to liberal quantities of hot water. For "a night out" nothing was superior to two or three cups of hot water, along with a cup or two of hot coffee. It soothed the nervous system if we abstained from food a few hours. We needed water for nutrition and,

what was more important, for proper elimination. Water taken freely acted as a purifier of the system, both by flushing and by its solvent action. The majority of people drank too little water. He strongly advised training children to drink more water. It was a most important agent in improving the complexion. Medicine should be given in large quantities of water. In typhoid fever he insisted upon the free drinking of pure water. No solvent would act better in removing uric acid from the system. The only pure water was distilled water. Copious draughts of water for its stimulating effect or the reduction of temperature had been used many years. The hot pack in the convulsions of children was often misused. It was better to begin with a tepid heat and add cold water gradually. Hot water applied locally in inflammatory conditions was most excellent.

Dr. MANLEY, of New York, thought that if we only realized what could be accomplished with water in a medicinal way, its use would be more general. He was much impressed with the fact that many of the bowel and bladder conditions could be most effectively treated by the proper use of water. In the case of cystitis he knew of nothing that would take the place of water. He had often thought that the surgeon's knife might be laid aside if he knew how to use water. A large number of the cases of perityphlitis, in his opinion, might be relieved by a thorough washing out of the bowel.

Dr. HUGHES, of St. Louis, said that water was good not only "the next morning," but all the time. Its value had not been overdrawn by the author or in the discussions. He was opposed to limiting the amount of water used at and during the mealtime. Its action was not only eliminative, but stimulating to both kidneys and bowels. He recalled the time when the profession went to the other extreme concerning this subject, and said they considered the craving for water by the patient as abnormal. Some of us had repudiated water too much and too long.

Dr. STUCKY, of Louisville, remarked that he could not give a "next-morning" experience like his predecessors, but he would say a word in favor of hydrotherapy. He took issue with the author on the idea that large quantities of water should be taken along with the food. He could not see how it would increase or aid in the digestive function in the stomach, but its importance after digestion could not be overrated.

Dr. BABCOCK, of Chicago, thought that in some cases of Bright's disease a sufficient quantity of water might have prevented the condition. If the bowels were constipated and the skin was dry, increased water was thrown upon the kidneys. Professional men, men of sedentary habits, and women would often escape the severity of Bright's disease by the unlimited use of water.

Dr. HENDERSON, of St. Paul, inquired whether or not the taking of large quantities of water would increase the fat formation. Did the fat man take water because he was fat, or was he fat because he took water? He himself was a lean man and did not drink water, except in the morning.

Dr. TURCK, of Chicago, said that the first indication was to find out what the pathological conditions were which we were trying to meet by the water treatment. We must know the condition of the stomach before advising the ingestion of large quantities of water. The habit of taking great quantities of water into the

stomach, even two hours after a meal, would hinder the process of digestion. On the other hand, if there was an accumulation of material on the walls and other viscera, then the taking of water would not be objectionable.

Dr. LOVE said, in regard to Dr. Henderson's question, that what was taken into the stomach was food and became nutrient and led to development, continued health, repair, and elimination; in these processes water had an important part, if taken in the right way. He did not advise that large quantities of water should be taken while a person was eating; moderate quantities, of course, were meant, and they could not possibly interfere with the digestive processes.

**The Relationship of Diagnosis to the Future Surgical Progress.**—This was the subject of an address on surgery, by Dr. HORACE H. GRANT, of Louisville. Some common ground, said Dr. Grant, must be chosen on which we could equalize our differences. Many of the most recent operations were already passing away under the effect of our modern scrutinizing investigation. We forgot there were men in the quiet of their laboratories doing a work which made all our wonderful progress possible, and gave us these new methods. We could not progress much further in technics or operative skill. Any great amount of paraphernalia suggested a lack of personal resource in the operator. Almost every part and organ of the human body had been removed recently with more or less good to the patient. If we would make earlier and more careful diagnoses many of the possible failures would be precluded. No surgeon dared to say to the patient: "If I had known yesterday or the day before thus and so, the result would have been different." Were we not at fault sometimes ourselves? Rarely should we fail to secure an operation if the operator was certain of his diagnosis and demanded the operation. No term in all surgery was so often misapplied as conservatism. No aim was dearer to the surgeon than the ways and means of relieving his patient. The skiagraph had lately come into importance in surgical work, and it might be made an excellent adjunct in many instances. Its recent successes were noteworthy. It was yet, however, in its infancy, and doubtless was capable of still more development. Might we not soon expect to see the *fœtus in utero*? No one doorway could open to the royal road to success in the practice of surgery. The skillful and intelligent application of prompt relief, added to a careful diagnosis, would give us the most wonderful and satisfactory results. What each one found to do, let him do it with his might.

**Appendicitis; to Operate or not to Operate.**—Dr. JAMES H. DUNN, of Minneapolis, said that if we could but foretell which of our cases were going to be fatal, we could much more easily and satisfactorily decide this question. The percentage of fatality was yet too high. But must we cease operating because of such a fact? In a certain number of cases recovery would occur without surgical interference. Indeed there was so large a number of such cases that he believed we very often, in our enthusiasm, operated when it would have been much better to leave them alone, so far as the knife was concerned.

Dr. J. B. MURPHY, of Chicago, said that the surgeon was brought face to face with a condition which had a recognized mortality of about from five to eight per cent. He thought such a percentage was too high. We first had to contend with the presence or absence of

suppuration. In four hundred and fifty cases, he did not think there had been an entire absence of pus in a single instance. He was satisfied that there were some patients who could be cured by medicine, but, he asked, could they be distinguished? Medical treatment gave a mortality of ten per cent., and if the knife gave three per cent., then we must operate to save the seven per cent. He thought that every patient could not be operated upon, but the conditions would show whether or not an operation was advisable.

**The Clinical Significance of the Child's Fontanelle.**—Dr. ISAAC A. AET, of Chicago, said that in health the fontanelle did not sink below or rise above its bony frame. It had both respiratory and pulsatory movements. With increased intracranial pressure the normal bruit might quite disappear. Early ossification interfered with brain development and produced brachycephalism. In rachitis the involution of the fontanelle was delayed. Marked bulging was caused by the collection of fluid within. Abnormal retraction of the fontanelle always indicated a condition of inanition. It might be temporary; if it was chronic it was a serious condition. A deeply sunken fontanelle was always a danger signal. Involution occurred normally at from fifteen to eighteen months. Protuberance and tension indicated meningitis.

**The Operative Treatment of Pterygium.**—This<sup>a</sup> was the title of a paper read by Dr. EDUARD BOECKMANN, of St. Paul, in which the author discussed the history of the operations for the cure of pterygium, and pointed out the objections as well as the advantages of those most frequently used. He suggested an operation which was a combination of some others referred to. A crescentic piece was cut from the pterygium, about five lines from its head. This part was curetted thoroughly down to the sclerotic. The head of the pterygium was dissected off. At the convexity of the piece cut out a stitch was inserted and the opposing edges were drawn together. This left the curetted portion to granulate and form a cicatrix. The author thought that the results of this method were superior to those of any other in his experience.

**Subconjunctival Injection in the Treatment of Certain Diseases of the Eye.**—Dr. WILLIAM H. WILDER, of Chicago, said this method consisted in the injection, beneath the conjunctiva, of minute quantities of bichloride of mercury or cyanide of mercury in solution. The operation was not especially painful unless there was inflammation. It had been advocated for many other conditions and diseases. Its exact limitations and indications were not yet positively decided upon. It had been impossible to get the same good results from the salt injections that could be obtained from the mercury. We had in this new treatment a powerful adjunct to the old and tried methods in some diseases of the eye. It was not to be employed to the exclusion of all others. It was not a panacea, but in cases in which mercurial treatment was indicated it was an excellent method.

Dr. BUCKNER, of Cincinnati, said he could not see the special advantage in injecting the solution of mercury under the conjunctiva over the old method of administering it hypodermically or through the mouth. The value of mercury in many cases of irido-chorioiditis could not be overestimated.

Dr. BOECKMANN stated that he had used these injections since he first began to practise medicine, but at this time he was unable to say just how much good they

really did. He carefully injected these solutions whenever he found an ulceration of the cornea. In some cases the method acted beautifully, in others it was a failure.

**Rupture of the Chorioid Coat.**—Dr. JAMES H. BUCKNER, of Cincinnati, said that the length of time which elapsed between the date of the accident and impairment of vision was no criterion by which to judge of the amount of damage done to the chorioid. The rarity of rupture of the chorioid was due to the elasticity of the coats, together with the soft and elastic cushion of fat upon which the eyeball was supported.

**Ether and Chloroform; their Comparative Merits as Agents for the Production of General Anæsthesia.**—Dr. W. S. CALDWELL, of Freeport, Illinois, gave an extended résumé of the statistics of death from chloroform and ether, and stated his preference for chloroform and the reasons therefor.

**The Use of Oxygen in Chloroform Narcosis.**—Dr. C. B. PARKER, of Cleveland, in a paper on this subject, said that the administration of the vital principle, oxygen, with chloroform would seem to be proper on theoretical grounds. On uniting the two there was no chemical union formed between them. It was a mechanical mixture such as we had in the air. The oxygen must be perfectly pure. That usually supplied in tanks was not pure. It must be properly made. The cylinder must be exhausted of all air before it was filled.

The time required to anesthetize was slightly longer than with chloroform, but the advantages far outweighed this minor inconvenience. Of the dangers attendant upon it he was not prepared to speak, as he did not consider that an experience of a hundred and eighteen cases guaranteed any statement relative to that point. There was total absence of vomiting, as well as absence of the extreme pallor and weakened heart-beats, with shallow respiration. The duration of the shock from anæsthesia with this agent was very much shorter. The patient always recovered promptly without any delirium.

**Syphilis as an Ætiological Factor in the Production of Tabes Dorsalis.**—This was the title of a paper by Dr. C. TRAVIS DRENNEN, of Hot Springs, Arkansas.

**Diseases of the Nose and Throat in Children.**—Dr. W. F. BARCLAY, of Pittsburgh, dwelt particularly on the possible results of acute and chronic purulent and mucopurulent rhinitis in children. He not only pointed out the necessity of more attention by the family physician, but demonstrated as well that almost all, if not all, the pathological conditions in the nose which occurred in later life had their origin in this condition in childhood.

Children should be taught to breathe through the nose rather than the mouth. Parents should be taught that surgery could relieve, very easily, those who were unable to breathe through the nose.

Dr. LOVE called attention to the necessity of watching over the child from earliest infancy and of teaching it to care for its nose. Many infectious diseases no doubt had their port of entry through this organ.

Dr. LOEB indorsed the author's views and emphasized the fact that too often indeed the children were blamed for having noses that "ran," through which they did not breathe when they could not possibly avoid it.

Dr. COULTER said that the author's idea of the etiology of deflected septum was one which he had advocated some years ago before the Illinois State Medical Society. He was convinced that there must be some other causes of a deflected septum than the bumps that babies re-

ceived. In stenosis of any degree there was created within the cavity a more or less complete vacuum with each inspiration. Thus the atmospheric pressure was to that degree increased and was a constant force of no inconsiderable gravity.

**A Surgical Melange.**—This was the title of a paper by Dr. J. MERRILL RICKETTS, of Cincinnati, in which he related the following cases: *Ligation of the Brachial Artery.*—Secondary hemorrhage had occurred six days after an accident. Five days later another severe hemorrhage had occurred. The middle brachial artery had been ligated at that time. Six days later a third hemorrhage had occurred. Erysipelas had followed and recovery had been uninterrupted. The superior profunda and its branches had been the source of the hemorrhage after the ligation of the brachial. The ligatures should have been applied above the superior profunda.

*Gunshot Wound Dividing the Facial Artery.*—Roller compresses had been sufficient to control the hemorrhage. Multiple abscesses had appeared on the cheek subsequently, one of which had left a salivary fistula. This fistula had been finally closed by the introduction of a silver wire.

*Talipes Equino-Varus with External Deformity.*—Phelps's operation had been done a year previously, with but slight improvement. The astragalus had been removed five weeks later through the dorsum of the foot. Division of the tendo Achilles had not been necessary.

*Hypertrophied Prostate.*—On the twenty-fifth day of a severe attack, double orchidectomy had been done under cocaine anesthesia. Dr. Ricketts had found that cocaine would answer every purpose in these cases. This was the third case in which the same operation had been done, and all had been successful.

*Sarcoma of the Sacrum.*—There had been present a syphilitic diathesis. The growth had been previously diagnosed as a fatty tumor. Complete removal had been followed by a prompt recovery, leaving a fistula from the rectum into the cavity. This had been successfully closed by a later operation.

Papers were also read by Dr. FENTON B. TURCK, of Chicago, A Further Report on the Treatment of Five Hundred Cases of Gastritis; Dr. CASEY A. WOOD, of Chicago, on Some Rare Forms of Keratitis; Dr. A. E. STEARNE, of Indianapolis, on The Significance and Occurrence of Capillary Pulsation in Nervous Diseases; and Dr. G. I. CULLEN, of Cincinnati, on The Newer Remedies in Otology and their Results.

## Book Notices.

1 *Practical Treatise on Materia Medica and Therapeutics.* By ROBERTS BARTHOLOW, M.A., M.D., LL.D., Professor Emeritus of Materia Medica, General Therapeutics, and Hygiene in the Jefferson Medical College of Philadelphia, etc. Ninth Edition, revised and enlarged. New York: D. Appleton and Company, 1896. Pp. xx-866.

This edition of Professor Bartholow's well-known work is larger by forty-five pages than its immediate predecessor, and a great portion of the additional matter is devoted to new drugs, chiefly the synthetical

chemical products, most of which are proprietary. In the preface Dr. Bartholow says with regard to these drugs: "When by the substitution process a remedy is evolved that seems likely to possess certain powers, it is placed in the hands of some friendly investigator to study its physiological actions, and it is then duly exploited by the manufacturer. It is undeniable that many important contributions have been thus made to practical medicine; but it is equally true that many have not sustained the pretensions of their promoters, and have either failed entirely of recognition or have only in part justified the extravagant claims made for them. The whole subject is yet hardly in a state to select out of the mass those that time and further clinical experience must justify." It seems to us that this expresses the feeling that any unprejudiced reader of current medical literature must entertain.

The work maintains its excellent character, and its continued popularity is well deserved.

4 *Vest-Pocket Medical Dictionary.* Embracing those Terms and Abbreviations which are commonly found in the Medical Literature of the Day, but Excluding the Names of Drugs and of Many Special Anatomical Terms. By ALBERT H. BUCK, M.D., New York city. New York: William Wood and Company, 1896. Pp. vi-529.

QUITE an extensive vocabulary has been got into this diminutive book, which may indeed be carried in the waistcoat pocket. Dr. Buck's definitions are, as a rule, very satisfactory, and we have noticed but very few errors of any kind. It is to be presumed that it is only by a proofreader's oversight that the expression "names of drugs and of [sic] many special anatomical terms" appears on the title-page.

## BOOKS, ETC., RECEIVED.

*Medical Jurisprudence, Forensic Medicine, and Toxicology.* By R. A. WITTHAUS, A.M., M.D., Professor of Chemistry, Physics, and Hygiene in the University of the City of New York, etc., and Tracy C. Becker, A.B., LL.B., Professor of Criminal Law and Medical Jurisprudence in the University of Buffalo. Volume Four. New York: William Wood & Company, 1896. Pp. 5 to 892.

*Preventive Medicine.* A Brochure for the Laity. Being a Practical Treatise on the Theory and the Technique of the Prevention of Disease. By Dr. Clarence Rutherford Hendrickson, County Physician of Canadian County, Oklahoma. Wichita, Kansas: Press of the Wichita Eagle, 1896. Pp. 9 to 75.

*Nouveaux éléments d'ophtalmologie.* Par H. Truc, Professeur de Clinique ophtalmologique à la Faculté de Montpellier, et E. Valude, Médecin de la Clinique ophtalmologique nationale des Quinze-Vingts. Tome Second. Avec 108 figures. Paris: A. Maloine, 1896. Pp. 713.

*Biblioteca Botanico-Mexicana. Catalogo bibliografico, biografico y critico de autores y escritos referentes a vegetales de Mexico y sus aplicaciones, desde la conquista hasta el presente. Suplemento a la Materia Medica Mexicana publicada por el Instituto Médico Nacional. Escrito por el Dr. Nicolas Leon, Fundador y ex-Director del Museo Michoacano, etc. Mexico: Oficial Tip. de la Secretaria de Fomento, 1896. Pp. 3 to 372.*

Report of the Commissioner of Health of Mil-

waukee, for the Years 1894 and 1895, together with the Report of the Board of Trustees of the Emergency Hospital. April, 1896.

Transactions of the South Carolina Medical Association. Forty-sixth Annual Meeting, April 22 and 23, 1896.

Transactions of the Seventh Annual Meeting of the Medical Society of the State of Washington, May 19 and 20, 1896.

Trichomonas Vaginalis. By N. S. Davis, M. D., Chicago. [Reprinted from the *Chicago Medical Record*.]

The Diagnosis of Tuberculosis from the Morphology of the Blood. An Original Research, with a Report of Cases. By A. M. Holmes, M. D., of Denver. [Reprinted from the *Medical Record*.]

The State of the Gastric Mucosa in Secretory Disorders of the Stomach. By Max Einhorn, M. D. [Reprinted from the *Medical Record*.]

The Fate of Micro-organisms in Inspired Air. By St. Clair Thomson, M. D., London, and R. T. Hewlett, M. D., London. [Reprinted from the *Lancet*.]

Local Hot-air Treatment in Rheumatism and Allied Affections. By W. Knowsley Sibley, M. D., London. [Reprinted from the *Lancet*.]

Sulla sede e sulla natura del morbo di Erb. Dott. Antonio Beorchia-Nigris.

Die Behandlung der Lungentuberkulose mittels Ichthyol. Von Dr. Moritz Cohn, in Hamburg. [Sonderabdruck aus der *Deutschen medicinischen Wochenschrift*.]

Ueber die beim Scheintod Neugeborener vorliegenden Indikationen. Von B. S. Schultze, in Jena. [Sonderabdruck aus dem *Centralblatt für Gynäkologie*.]

Die Hygiene in den Barbierstuben. Von Dr. Heinrich Berger, Hannover. Basel und Leipzig: Carl Talmann, 1896. Pp. 7 to 32.

A System of Gynæcology. By Many Writers. Edited by Thomas Clifford Allbutt, M. A., M. D., LL. D., F. R. C. P., F. R. S., F. L. S., F. S. A., Regius Professor of Physic in the University of Cambridge, etc., and W. S. Playfair, M. D., LL. D., F. R. C. P., Professor of Obstetric Medicine in King's College, etc. New York and London: The Macmillan Company, 1896. Pp. xviii-973. [Price, \$6.]

Manual of Diseases of the Ear, including those of the Nose and Throat in Relation to the Ear. For the Use of Students and Practitioners of Medicine. By Thomas Barr, M. D., Lecturer on Diseases of the Ear, Glasgow University, etc. Second Edition, entirely revised and extensively rewritten. With Two Hundred and Twenty-nine Illustrations. New York: The Macmillan Company, 1896. Pp. xxiii-415. [Price, \$3.50.]

Anatomical Atlas of Obstetrical Diagnosis and Treatment. By Oscar Schaeffer, M. D. With One Hundred and Forty-five Illustrations. New York: William Wood and Company, 1896. Pp. xvi-234.

A Pictorial Atlas of Skin Diseases and Syphilitic Affections, in Photo-lithochromes from Models in the Museum of the Saint-Louis Hospital, Paris. With Explanatory Woodcuts and Text by Ernest Besnier, Physician to the Saint-Louis Hospital, etc.; Tenneson, Physician to the Saint-Louis Hospital; Hallopeau, Member of the Academy of Medicine, etc.; and Du Castel, Physician to the Saint-Louis Hospital. With the Cooperation of Henri Feulard, Curator of the Museum, and Leon Jacquet, Secretary of the Dermatological Society of France. Edited and annotated by J. J. Prin-

gle, M. B., F. R. C. P., Assistant Physician to and Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. London: F. J. Rebman. Philadelphia: W. B. Saunders, 1896. Part V. Pp. 113 to 137. [Price, \$3 each part.]

Essentials of Physical Diagnosis of the Thorax. By Arthur M. Corwin, A. M., M. D., Demonstrator of Physical Diagnosis in Rush Medical College, etc. Second Edition, revised and enlarged. Philadelphia: W. B. Saunders, 1896. Pp. 17 to 199. [Price, \$1.25.]

Ophthalmic Operations as Practised on Animals' Eyes. By Clarence A. Veasey, A. M., M. D., Adjunct Professor of Diseases of the Eye, Philadelphia Polyclinic, etc. With Fifty-six Illustrations. Philadelphia: The Edwards & Docker Company, 1896. Pp. viii-9 to 99.

Sojourn among the Oculists of Europe. By Flavel B. Tiffany. Kansas City, Missouri: Hudson-Kimberly Publishing Company, 1896. Pp. 5 to 125.

Over the Hookah. The Tales of a Talkative Doctor. By G. Frank Lydston, M. D., Professor of Criminal Anthropology in the Kent College of Law, etc. Illustrated from the Author's Designs by Mr. C. Everett Johnson. Chicago: Fred. Klein Company, 1896. Pp. xix-25 to 618.

The Philosophy of Sex. By H. Edwin Lewis. Burlington, Vermont: The Vermont Medical Publishing Company, 1896. Pp. 7 to 51.

The Medical Record Visiting List or Physician's Diary for 1897. New Revised Edition. New York: William Wood & Company, 1896.

The Medical News Visiting List for 1897. Philadelphia: Lea Brothers & Co., 1896.

Die Versorgung von kleineren Städten, Landgemeinden und einzelnen Grundstücken mit gesundem Wasser. Von Dr. F. Kraschutski, Stabsarzt in Danzig. Mit 4 Figuren im Text. Hamburg und Leipzig: Leopold Voss, 1896. Pp. 40.

## Miscellany.

**The Modern Treatment of Diphtheria in Private Practice.**—In an article on this subject in *Pædiatrics* for October, Dr. W. A. Walker states that the uniform success which he has observed and obtained in his own practice has convinced him that the treatment of diphtheria with antitoxine is a great advance in therapeutics, and it is his impression that those who have condemned this treatment have in most instances observed only hospital patients, or have not persisted in the treatment, or perhaps have not had a fresh and reliable serum, or have not used it early enough. The author states that, from the standpoint of a general practitioner, he fully expects to cure any patient with diphtheria in private practice if he is seen within forty-eight hours after the onset of the disease.

In typical cases, says Dr. Walker, the physician finds the following conditions: General depression, the face pale, the pulse accelerated, and the temperature about 101° F. An inspection of the throat reveals general diffuse redness, with the characteristic deposit on one or both tonsils. This peculiar deposit once seen is not readily forgotten. The high fever, flushed face, and rapid pulse usually seen in pseudo-membranous amygdalitis are absent; the margin of the inflammatory process is usually sharply defined in diphtheria and not in amygdalitis. In follicular amygdalitis the leading symptoms are intense congestion of the tonsils, with small discrete white patches, and the pulse and temperature high.

If, however, the symptoms are not well defined and the diagnosis can not be clearly made, the patient should be given the benefit of the doubt and a dose of anti-diphtheritic serum administered at once. Then a culture should be made to verify the diagnosis. If the author believes the case to be one of diphtheria, or has a reasonable doubt as to the diagnosis, he uses the antitoxine while waiting for the report from the bacteriologist. If the case turns out to be one of amygdalitis, no harm has been done, he says, as he considers a fresh, reliable serum, properly administered, devoid of danger.

In a case where the diagnosis of diphtheria is clear, he gives as quickly as possible either 1,000 or 1,500 units of the serum. The attendant is instructed to keep the throat clean with a bichloride solution of 1 to 5,000, or a solution of permanganate of potassium may be used, 1 to 4,000, if the attendant is not a trained nurse. With a young child, difficult to manage, it is best to inject the solution into the nostrils; in older children a spray can be used in both the nostrils and throat more advantageously.

At the end of twenty-four hours the membrane should begin to shrivel and curl up at the edges. In any event, however, he administers a second injection at this stage of the disease, and in a majority of instances this is sufficient. He advises very strongly that the second injection should be given in all cases where the diagnosis of diphtheria is clear. He does not expect a cure from one injection, and rarely omits the second. If the symptoms do not indicate the beginning of convalescence at the end of forty-eight hours, he gives a third injection. In fact, he says, he would use a fourth injection if it seemed advisable at the end of another twenty-four hours, but he thinks this will rarely be found necessary.

He states that he has not used antistreptococcic serum, but he is convinced that in cases in which the treatment has been delayed, or in cases showing the streptococcic infection, proved by bacteriological investigation or by the peculiar red zone of inflammation which begins to spread from the margin of the diphtheritic process, the antistreptococcic serum should be used promptly. Not only this ought to be done, but in cases of severe acute disease in the throat, which present all the symptoms of diphtheria, but where the bacteriological report does not confirm the diagnosis, the antistreptococcic serum should be resorted to. In fact, if he should have a case of diphtheria in which the membrane did not begin to peel up by the end of the twenty-four hours following, say, the second injection of antitoxine, he adds, he would use the antistreptococcic serum.

Dr. Walker insists upon the importance of a fresh,

reliable, highly concentrated serum, and states that he has full confidence in the American products and does not use imported serums. He has used several serums, but has been best satisfied with the effects of that sent out from the biological department of Parke, Davis, & Co., and heartily approves of the way in which this firm now puts up the serum in bulbs instead of in bottles. It not only is highly concentrated, but, being hermetically sealed, should keep indefinitely. It is put up in bulbs of so many units, 250, 500, 1,000, and 1,500, and, each bulb containing a dose, there is no temptation to use a serum that has been exposed to the atmosphere.

Dr. Walker gives a detailed tabular report of the last seven cases which he treated in private practice. Bacteriological cultures were made in five. From two to three doses of antitoxine were given on the first, second, and third days after the first appearance of the disease. Intubation was practised in two cases. Recovery occurred in all the cases.

As to the medicinal treatment, he continues, he does not give any drug with the idea of influencing the course of the disease. He treats the conditions as they arise symptomatically. If he has evidence of the absorption of poisonous secretions, and there is a coated tongue, he gives calomel tablet triturates, a quarter of a grain every hour, until the bowels move freely. Alcohol is rarely needed in cases in which the serum treatment is employed, especially if it is used early enough, whereas under the old treatment, when we were so apt to find profound toxic symptoms, alcohol was often needed. Dr. Walker states that he prefers fluid nourishment, principally milk, during the course of the disease.

**Sparteine Sulphate in Surgical Anæsthesia.**—In the *Therapeutic Gazette* for November Dr. Gilbert G. Cottam states that he has employed sparteine sulphate in a number of surgical cases with very positive results, the beneficial effect of the drug being clearly shown in nearly every instance.

The effect of sparteine on the heart was first noticed by Laborde, whose observations were subsequently confirmed by Griffe, Garaud, and Masius. Germain Sée first drew attention to its great value in cardiac affections; and finally, in America by Cheves Bevil, in France by P. Langlois and Maurange, the remarkable properties of the sulphate as a cardiac stimulant in chloroform narcosis were observed and described.

Bevil (*Therapeutic Gazette*, vol. xix, p. 71) uses it in doses of a fifth of a grain by the mouth, given thirty minutes before the chloroform is administered. He describes two cases in which the patients did well throughout prolonged anaesthesia.

Langlois and Maurange (*Semaine médicale*, August, 1894) give from 0.5 to 0.6 of a grain of sparteine sulphate and three twentieths of morphine hypodermically, fifteen minutes before the commencement of anaesthesia. They have done this a hundred and twenty times on the human subject. In many of these cases the patients suffered from heart disease or had to undergo prolonged operations, such as laparotomy, ketotomy, and reduction of dislocations. In all of them the heart-beats continued full and perfectly regular.

The author's mode of procedure is to inject hypodermically a tenth of a grain of sparteine sulphate ten minutes before the anaesthesia is begun. Then, if the operation is protracted, a fifteenth of a grain is injected during its progress. These doses have been found ample

to secure the desired effect, although they are much smaller than is generally considered necessary.

Dr. Cottam gives an account of seven cases to illustrate the points enumerated. Sparteine sulphate was used in every instance in the manner just described, and the patients themselves, from various causes, were such as would be peculiarly susceptible to the depressing influence of chloroform, and hence admirably adapted to demonstrate the properties of sparteine.

A study of these cases and many others of a minor nature, he says, has caused him to form these conclusions:

1. That in sparteine sulphate, administered hypodermically before the beginning of anæsthesia, in the dose of a tenth of a grain, repeated according to the nature of the operation and the condition of the patient, we have a safe, efficient, and prompt heart stimulant in chloroform narcosis.

2. That it is not necessary either to combine it with morphine or to use it in larger doses than those specified.

3. That, other things being equal, there is less shock and there is prompter reaction with its use.

**Strontium Lactate in Bright's Disease.**—According to the *British Medical Journal* for November 7th, Brouowski (*Wiener medicinische Presse*, September 13, 1896) gives a preliminary account of the results of his clinical and experimental investigations into the action of strontium lactate upon the kidneys. His first experiments were upon rabbits, and consisted in the daily subcutaneous injection of a quantity equal to double the dose in proportion to the body weight. After a month one rabbit had gained seven ounces in weight, and the second ten ounces, while the third had not altered. They were perfectly well in every way, and after they had been killed the internal organs were found to be normal. The drug was then tried in ten cases of kidney disease, three of which were acute parenchymatous nephritis, six mixed nephritis, and one interstitial nephritis. Six doses of fifteen grains were given daily, and well borne. In all cases the volume of the urine increased, and its specific gravity fell. This effect began on the second or third day, and was most marked on the sixth or seventh, and persisted two or three days after the drug had been discontinued. The action was most marked in acute cases, and was much slighter in the chronic forms; the albumin diminished *pari passu* with the increase in the urine. In acute cases it disappeared entirely, but in chronic no diminution was observed. The ethereal sulphates in the urine, by which the amount of intestinal putrefaction may be estimated, were unaffected, and there was no constant change in the pulse or blood pressure. The antiseptic properties of lactate of strontium were tested upon a patient with an intestinal fistula in the cæcal region, and found to be extremely slight. A further series of experiments was made upon dogs, solutions of the drug of various strengths being injected intravenously. The blood pressure was at first unaltered, but fell rapidly when the dose was increased; the rapidity of the pulse and respiration was increased; and the volume of urine was doubled or tripled. With enormous doses the volume again diminished and the urine was found to contain red and white corpuscles. In this case there were seen post mortem (the animal having been killed by bleeding) hyperæmia of the kidneys and hæmorrhages into their capsule and parenchyma. The author concludes that stron-

tium lactate is a pure diuretic, and is more valuable than any other remedy in the treatment of acute inflammatory conditions of the kidney.

**A Peculiar Eruption from Contact with Arterial Blood.**—In the November number of the *British Journal of Dermatology* Mr. Marmaduke Sheild states that he has noticed a peculiar skin manifestation which appears in consequence of arterial blood forcibly spurring and drying upon an exposed surface. He has principally observed it, he says, upon the backs of his own forearms and upon his forehead after operations attended with hæmorrhage, in which the skin is spattered or speckled with arterial blood. On his washing away the little crusts of dried blood, a faint pink erythematous spot appears in the site of each; this darkens to a faint red, lasts about half an hour, and finally slowly disappears. The rash is not attended by itching, burning, or inconvenience. He has observed it so frequently in his own person that there can be no doubt of its occurrence. He has also seen it upon the forearms of his assistants, though not so vividly marked as upon his own. He has twice noted it upon the exposed skin round the breast in cases of removal of that organ. He states that it certainly is not constant, and this makes him believe that the cause is to be found in some peculiar condition of the blood. On one occasion it was remarkably vivid upon the back of his forearm after washing away the arterial speckling contracted in the excision of a tuberculous knee. He has often shown it to the house surgeons, who are familiar with its appearance on his own arms. The author says he is quite unable to explain its occurrence, and thinks an unusual phenomenon of this kind is worthy of the attention and investigation of others. He has no doubt it will be commonly found, and he proposes for the time to apply to it the appellation of "blood erythema."

**Tuberculosis of the Tonsils in the Vegetative Form.**—In the *Revue hebdomadaire de laryngologie, d'otologie et de rhinologie* for November 7th M. Mouret remarks that since Dieulafoy maintained that he had demonstrated primary tuberculosis of the tonsils by inoculating guinea-pigs with fragments of these organs, and since Lermoyez had demonstrated histologically that adenoid vegetations of the pharyngeal tonsils were sometimes tuberculous, the question of tuberculosis of the tonsils has become a subject of interest to physicians in general and laryngologists in particular. Having had occasion himself to remove some adenoid vegetations from the palatine tonsils of a young man, M. Mouret thought it would be of interest to record the case, of which he gives a detailed account. These vegetations were subjected to an examination; they were fixed in Roule's liquid and inclosed in paraffin, and the sections were colored according to Ziehl's method. The histological examination showed that the vegetations were filled with giant cells and presented a very large number of Koch's bacilli. An attempt was made, says the author, to photograph the bacilli, but the results obtained were not distinct enough, and a drawing was made which represents an enormous giant cell with its jagged periphery and the numerous peripheral shells which characterized it; all around this cell there was a thick band of leucocytes; in its interior two bacilli were found, which, in the colored preparations made by Ziehl's method, became of a red color from the fuchsine, which fixed them more strongly than the other elements of the preparations. The bacilli were

also seen in the neighboring tissues, which showed symptoms of necrosis.

M. Mouret thinks that the histological examination fully demonstrated the tuberculous nature of these vegetations, and he calls attention to this vegetative and non-ulcerative form of tuberculosis of the tonsils.

Concerning the question of primary or secondary tuberculosis in this case, M. Mouret states that at the time he saw the patient there was nothing to cause him to suppose that there was primary tuberculosis. The condition of the larynx led him to think, on the contrary, that it must have been secondary, as is more often the case. But, he says, granting the advanced tuberculous condition of these vegetations, it may also be questioned whether this vegetative tuberculosis was not primary. At all events, it may be admitted *a priori* that this may be the case more frequently than we are aware of, and that the tonsils may be tuberculous before any other organs are attacked by Koch's bacilli. Since Lermoyez has shown that adenoid vegetations of the pharyngeal tonsils may be tuberculous without manifestations of tuberculosis elsewhere, it is rational enough to admit that this may be the case in the palatine tonsils. However, continues M. Mouret, if tuberculosis of the palatine tonsils is admitted at the present time, the demonstration of primary tuberculosis of these organs has not yet been sufficiently established; this is owing, no doubt, he says, to the fact that histological examinations of the parts removed are not made often enough. Such an examination only can reveal whether a vegetation of the tonsils, or an hypertrophied tonsil in a mass, in a child or an adult who has no tuberculous manifestation elsewhere, is of a bacillary nature. It is not sufficient to inoculate fragments of a diseased tonsil under the skin or in the peritoneum of a guinea-pig in order to establish, if the animal becomes tuberculous, that this tonsil was tuberculous. So many microbes constantly inhabit the buccal cavity that Koch's bacilli may certainly be found lodged in the tonsillar crypts.

In this case, says M. Mouret, their presence in the lower part of the crypts and outside of the tonsillar tissue may suffice to produce tuberculosis in the inoculated animal. Only a histological examination can indicate clearly the tuberculous condition of the tonsil.

**The New York Civil Service Commission** will hold the following examinations at its office, in the New Criminal Court Building, at 10 A. M. on the dates named. Citizens of the United States who are residents of the State of New York and hold the degree of M. D. are eligible for these examinations. Applications may be obtained from S. William Briscoe, secretary, New Criminal Court Building, New York city.

**December 3d.**—Medical chief of staff, Department of Public Charities. Candidates must hold the degree of M. D. and have experience in hospital organization and management. Salary, \$3,000 per annum.

**December 15th.**—House physician, Bellevue Hospital, Department of Public Charities. Candidates must hold the degree of M. D. They will be examined on nervous and mental diseases. Salary, \$1,200 per annum.

**The New York Academy of Medicine.**—At the last meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 25th inst., the following cases were presented: Laryngeal Stenosis, by Dr. J. W. Gleitsmann; A Tooth-plate from the Larynx, by Dr.

J. E. H. Nichols; Epilepsy cured by Nasal Operation, by Dr. T. P. Berens; and Frontal Sinus Disease; Operation and Cure, by Dr. T. J. Harris. New instruments and apparatus were exhibited.

**Sodium Nitrite in the Treatment of Syphilis.**—In the *Indépendance médicale* for November 4th there is an abstract of an article from the *Giornale italiano delle malattie veneree e della pelle*, in which the author, Dr. Florio Sprecher, states that M. Pétroué has recently tried sodium nitrite in the treatment of rabies and syphilis. The results were successful in the latter disease only, and the author, encouraged by this example, experimented with this new method. He used very pure sodium nitrite in solutions of from four to eight, twelve to sixteen, and twenty to twenty-five per cent. The injections were made daily, either into the subcutaneous tissue or deep into the muscles. During the first days only a few centigrammes were injected, but afterward the doses were progressively increased; the daily quantity never exceeded eight grains, and the treatment was never prolonged over thirty days. The injections never caused abscesses or left indurations.

The author states that among twelve women treated by him, two showed such an intolerance of the sodium nitrite that the treatment had to be given up. With regard to the others, the author is obliged to admit that the results obtained were entirely contrary to those published by M. Pétroué. There was no amelioration of the general condition and there was no increase in weight; the anæmia remained the same in five patients and was aggravated in the rest. The initial syphiloma and the lymphatic glands were not at all modified under the influence of this remedy, but the so-called rheumatoid and osteocopic pains, as well as the neuralgia from which the patients suffered were attenuated under the influence of sodium nitrite. On the other hand, in two men the osteocopic pains did not appear, except during the treatment. The cutaneous syphilides were aggravated, and those of the mucous membranes were not modified. Regarding the two cases in which this treatment was not tolerated, cyanosis, nausea, and vomiting were observed in one, and cyanosis and violent pain in the other. The author concludes that this remedy is not efficacious and, furthermore, that it presents the dangers of poisoning.

**Tattooing Effaced by Electrolysis.**—At a recent meeting of the Berlin Society of Dermatology, a report of which is published in the *Annales de dermatologie et de syphiligraphie* for October, Dr. Heller presented a patient in whom he had effaced the marks of tattooing on the hand with electrolysis. He had employed a current of three milliamperes, and the result was good. He had been obliged to proceed with a certain amount of caution in order to avoid exposing the entire region to electrolysis; but without local necrosis a cure was not possible. At all events, under these circumstances, Dr. Heller found it necessary to make from fourteen to twenty applications.

Recently, he said, good results had been obtained by washing the tattooed parts with a solution of tannic acid; needles were then plunged into the affected region, which was finally touched with silver nitrate so as to cause the formation of silver tannate *in situ*. Giovanni, in his microscopical examinations, found large vacuoles which were formed by electrolysis in consequence of destruction of the adipose layer. Dr. Heller thought that these cavities disappeared again very rapidly.

The following twenty-four groups of illustrations are from photographs of copper-plated plaster models.

### AIDS IN OBSTETRIC TEACHING.

By JAMES CLIFTON EDGAR, M. D.

(Concluded from page 707.)

#### IV. Miscellaneous Models and Aids.

A FEW metal and leather models, not classifiable under the other divisions of aids, I place under this heading.

FIG. 60.—Metal pelvis and tripod. Useful for demonstrating the mechanism of labor and obstetric operations. (From a photograph.)

1. *Aluminum Cast of Sagittal Mesial Section of Bony Pelvis.\**—The first that we have to offer is a vertical mesial section of the female bony pelvis, cast in aluminum and mounted by means of a hand screw upon a blackboard, and the whole set in a tripod. By means of a narrow nickel band the right half of the pelvic brim is completed, so that the pelvic inlet shows a continuous line without a break. Rotation on a transverse axis allows us, by means of the hand screw, to place the pelvis

\* Made by the John Reynolders Company, New York.

in the position corresponding to the dorsal and upright ones, or at any intermediate angle (see Fig. 1).

FIG. 61.—Leather model of the puerperal uterus, with double laceration of the cervix and opening at one side closed by tapes. Useful for many demonstrations. (From a photograph.) See Figs. 7 and 8.

Below the aluminum cast I have outlined permanently in white upon the board a vertical mesial section of the female bony pelvis, in the position corresponding to the dorsal one, and with the diameters and axes of the bony inlet and outlet and the axis of the parturient

FIG. 62.—Leather model of puerperal uterus, showing interior. (From a photograph.)

outlet added; such a combined blackboard and working model, we believe, has never been offered before, and without using it one can scarcely imagine the manifold and varied uses to which such a combination may be put, as the invention is equally useful in gynæcological as well as obstetrical demonstrations.

With a supply of puppets, models of uteri, and colored chalk at our disposal, there is scarcely an obstetric or gynecological condition that will not admit of a concise ocular demonstration.

FIG. 63.—Reproduction in rubber of a plaster cast, taken from Nature, of the buttocks and vulva. Useful for demonstrating the mechanism and management of the second stage of labor. (From a photograph.)

The metal pelvis (Fig. 70) can, with advantage, be used, in conjunction with the present sagittal section of the pelvis, in many ways that will readily suggest themselves to the demonstrator. If desired, the same tripod will answer for both contrivances.

FIG. 64.—External genital organs. Nullipara. From cadaver. (Copper-plated plaster cast; from a photograph.)

Fig. 1 shows the model and blackboard mounted upon the tripod, and Figs. 2 to 6 indicate a few of the many ocular demonstrations that may be given with it.

2. *Complete Metal Pelvis.*\*—The complete metal pel-

vis, mounted upon a tripod, has already been described and figured in a paper upon obstetric manikins\* but I take the opportunity of reproducing it here (Fig. 60).

Its utility is attested by the fact, as the instrument maker informs us, that it has been supplied to many of the medical schools of this country and Canada.†

3. *Leather Model of Puerperal Uterus.*‡—Such a simple and inexpensive model as that depicted in Fig. 61

FIG. 65.—Vagino-perineal laceration involving the right lateral sulcus. Two internal, or vaginal, and two external, or perineal, sutures in place ready to be tied. (Copper-plated plaster cast; from a photograph.)

can readily be made to do duty in various kinds of demonstration. It is constructed of chamois leather, lined with canvas, and may be opened along one lateral half, the opening being closed with tapes (Fig. 62).

\* Edgar. The Manikin in the teaching of Practical Obstetrics. *New York Medical Journal*, December 27, 1890.

† The following is the original description: For demonstrating the mechanism of labor before a large class—the application of the forceps, cranioclast, cephalotribe, and other obstetric instruments; the various methods of performing version; the different methods of manual extraction, whether by the head, shoulders, breech, or lower extremities—the gun-metal pelvis, covered with leather and mounted upon a tripod, has proved itself exceedingly useful (Fig. 60).

The pelvis is practically indestructible, and is so mounted (Fig. 60) upon the upright of a tripod as to permit of rotation in an entire circle in a horizontal plane, which allows the pelvic outlet or inlet to be directed to any point desired.

Besides complete rotation in the plane of the horizon, partial rotation upon a transverse axis is also easily and quickly secured, and a simple device (Fig. 60), in the shape of a small wheel at the side, enables one to fix the planes of the pelvis (represented by cardboard if need be) at any desired angle with the horizon.

If desirable, for greater convenience and accuracy, a simple scale may be added at the side, which will enable one to read off at a glance the angle produced. A movable coccyx permits recession during the passage of the fetus, and a spring throws it back again to its true position. A false sacrum, controlled by a thumbscrew passing through the true sacrum, enables one to illustrate contraction of the pelvis in its antero-posterior diameter, or to fix the presenting part of the puppet or fetal cadaver in any desired position.

‡ Made by the John Reynolds Company, New York.

\* *Ibid.*

The cuff of the partly cut away vagina is represented by a piece of leather, and the cervix made to show a bilateral laceration, extending in each instance as far as the uterovaginal junction.

The whole roughly resembles the puerperal uterus at the beginning of the puerperium.

This uterus can be utilized in a variety of ways: alone to show manual expression of the placenta; in conjunction with the metal pelves to demonstrate the axis of the puerperal uterus and puerperal canal and Credé's method of placental expression, or with any ordinary manikin, to illustrate the technics of various puerperal obstetric procedures. With this simple model, together with some gauze, volsella forceps, dressing forceps, needles, ligatures, curettes, and a speculum, the student may be made familiar with that manual training necessary to ligate the bleeding points in a deeply lacerated cervix; to pack safely the puerperal uterus with gauze to control hæmorrhage or secure drainage; to use properly the puerperal curette, so as to reach safely the fundus with the cautious upstroke, and to clear it of *débris* with the more forcible clean downward sweep, not neglecting to clear the cornua at the same time.

FIG. 66.—Vagino-perineal laceration involving both lateral sulci. Three internal, or vaginal, and two external, or perineal, sutures in place ready to be tied. (Copper-plated plaster cast; from a photograph.)

In order that the student shall acquire this manual training, it has been our custom to place the proper instruments in his hands and require him to carry out the

procedures above referred to. His handling of the curette is then criticised; the model is opened and the

FIG. 67.—Vagino-perineal laceration involving right postero-lateral vaginal wall and perineum to the sphincter ani. Four internal, or vaginal, and three external, or perineal, sutures in place ready to be tied. (Copper-plated plaster cast; from a photograph.)

manner of the gauze packing inspected, and if he has failed to reach the fundus with the gauze, his fault explained to him. So also the ligature in the cervical laceration is looked to, and the student's errors in technic corrected.

I have intended in this model to supply to the student the means and the opportunity to acquire that kind of manual training in certain obstetric procedures which may never occur to him until he is in active practice, and, moreover, the manual training that will save the physician's first cases of confinement much that would otherwise be but crude and experimental, if not actually dangerous, treatment.

Fig. 7 represents the use of the leather uterus in a manikin. The uterus, drawn down into the vulva by means of two volsella forceps, and is held by an assistant; with blunt-pointed dressing forceps the student proceeds to pack the uterus with gauze from a glass receptacle, the fingers and palm of the left hand being used as a trough to guide the gauze directly from the glass tube into the uterine cavity, thus avoiding all contact with adjacent unclean tissues.

Fig. 8 illustrates the uterus drawn down in the

same manner, and the student with needle and holder applying a ligature to a bleeding lacerated cervix.

ter cast in this model was first taken from the living subject, this in turn cast in iron, and from this latter rubber

FIG. 68. Laceration of right postero-lateral vaginal wall, perineum, and anterior rectal wall through the sphincter. Four rectal sutures and one silver wire suture, the latter trans-fixing torn ends of sphincter muscle and encircling apex of rectal laceration, in place and ready to be tied. (Copper-plated plaster cast; from a photograph.)

FIG. 69. Rectal sutures of Fig. 68 tied and cut short in rectum. Silver wire sphincter suture and four vaginal sutures in place and ready to be tied. (Copper-plated plaster cast; from a photograph.)

4. Rubber Perineum and Vulva.—In Fig. 63 is shown a rubber pelvic floor taken from Nature. A plas-

FIG. 70. Vaginal sutures of Fig. 68 tied. Three perineal sutures in place, ready to be tied. (Copper-plated plaster cast; from a photograph.)

models were made. It supplies the place of the ordinary manikin for class-room, clinic, or ward demonstration,

FIG. 71. Perineal sutures of Fig. 70 tied. Ends of deep silver suture trans-fixing sphincter muscle twisted. Ends of rectal sutures hidden by closed anus. Vaginal sutures seen to the right. (Copper-plated plaster cast; from a photograph.)

and has the additional advantage of being readily portable and capable of being kept perfectly clean.

### V. Electro-plated Plaster Models.

Experience has taught us that the *papier-mâché* method is not applicable for very small objects where minuteness of detail is required. I refer more particularly to the non-pregnant uterus, the pregnant uterus in the early months, conditions of the cervix, lacerations of the vagina and pelvic floor. We have therefore hit upon a method of illustration which has given the greatest satisfaction, and secures for us a model which is comparatively light, practically indestructible, and leaves nothing to be desired in accuracy of detail, as the original and permanent model is a plaster cast taken from Nature.

If, for example, a reproduction of the multiparous uterus is desired, as soon as possible after its removal from the cadaver a model in plaster of Paris is taken of it. From this model, subsequently, any number of casts or models may be reproduced. These are allowed to dry thoroughly, and are then sent to an electrotyper, who, at a trifling expense, throws a layer of copper over the plaster cast, and afterward the model can be colored in any desired manner. In this way were obtained the smaller uteri represented in Figs. 10 and 11, and the several degrees and varieties of perineal lacerations artificially produced upon the cadaver and represented in Figs. 64 to 71.

We need not confine ourselves to plaster as regards copper-plating, as bone, composition, and clay may be subjected to the same process. All the models of pelvic deformity (groups 1 to 24) were treated in the same way for the sake of strength and durability.

1. *Lacerations of Vagina, Perinæum, and Anterior Rectal Wall.*—My aim in this direction has been to produce a series of models that shall illustrate the ordinary degrees of vaginal, perineal, and rectal lacerations produced during childbirth. To this end at first I confined myself to plaster casts taken from the living subject at the completion of the puerperium. This proved unsatisfactory, however, because of contraction and distortion of the parts in question, so that the series herein offered represents plaster casts of artificially produced lacerations with the knife upon the cadaver. The positive mold being taken in plaster of the injury produced, a second positive in glue was taken from this, and then negative plaster casts taken from the glue positive and copper-plated. These latter are then completed by the insertion of sutures by means of an ordinary drill.

This series includes (1) a cast of the nulliparous genitals, showing the fourchette, from which the subsequent casts, with injuries, were secured (Fig. 64); (2) a vagino-perineal laceration involving the right lateral vaginal sulcus, with sutures for repair in position (Fig. 65); (3) vagino-perineal laceration, involving both lateral sulci, with sutures for repair in position (Fig. 66); (4) vagino-perineal laceration, involving right postero-lateral vaginal wall and perinæum to the sphincter ani, with sutures for repair in position (Fig. 67); (5) laceration of right

postero-lateral vaginal wall, perinæum, and anterior rectal wall through the sphincter, sutures for repair of rectal wall, and suture, including sphincter, in place (Fig. 68); (6) rectal sutures tied and cut short, wire sphincter suture ready to be tied, vaginal sutures in position (Fig. 69); (7) vaginal sutures tied, external perineal sutures in position (Fig. 70); (8) external perineal sutures tied (Fig. 71).

2. *Pelvic Deformity.*—The subject of pelvic deformity has always been one of the driest and most uninteresting to the student, and one of the most difficult for the instructor to teach. Little more than a temporary impression is made by diagrams, verbal and printed descriptions, and by perhaps an occasional clinical demonstration of some form of pelvic deformity, so that at graduation, and even later in the pupil's professional career, the various deformities, whether they be congenital or produced by rachitis, osteomalacia, ankylosis, or adventitious causes, too often escape notice until the patient is perhaps well in the first stage of labor. We have always believed that the best, if not the only satisfactory method for the pupil to acquire an intelligent appreciation of this subject is to place in his hands the various deformed pelves, and with the normal type in view before him require the student to point out the departures from the normal in the deformed pelvis. This can readily be made a stepping-stone to the causes of such abnormalities, the diagnosis and prognosis of the same, and the treatment appropriate to meeting the condition in pregnancy or labor. Commencing with the moderate deformities, the more marked and rarer conditions can then be gradually approached. So in the obstetric clinic, hospital ward, or the dispensary, examination of pregnancy, varieties of pelvic deformity, with their prognosis and treatment, can be brought home to pupils in a manner never before thought possible, if at our command we possess a series of deformed pelves from which one resembling, if not exactly corresponding to, the abnormality can be chosen. Heretofore this want we have been unable to meet in the recitation room or hospital. The limited number of specimens of pelvic deformity to be found in any single college or hospital museum are practically non-accessible to the student or practitioner, and surely are too valuable and fragile to allow of repeated handling and study.

Recently Tramond,\* of Paris, has completed a series of twenty-two deformed pelves.

This collection consists of twenty-two plaster models, with artificial ligaments added, being correct reproductions of the originals now in possession of private individuals or of the museums of Paris.

The series offers examples of the principal malformations, and there are in addition two pelves of normal conformation—namely, the male and female types, making twenty-four models in all.

\* Maison Vasseur, 9 rue de l'École de Médecine.

In a number of the titles of the pelves herein given is included the owner of the original or the museum where found. Such a collection has been of great help to us for several years past, and had we not hit upon some means to render the models more durable, would not at the present writing be presentable. To meet the wear and tear of repeated handling and demonstration, we have had these pelves sent to an electrotyper and a thin film of copper thrown over them. This copper-plating does not, to any extent, change the proportions of the original pelves, but renders them practically indestructible, and a coat of paint will easily restore the original natural appearance. Very slight additional weight is added, and the plated model can be cleansed and thus rendered free from suspicion for clinical or bedside demonstration.

Believing this series of deformed pelves to be of value not only to the teacher of obstetrics but to the general practitioner and surgeon as well, I have made it a basis of study, making complete measurements of each pelvis, offering a photograph of the pelvic inlet and outlet of each, an outline of a lead cast to show the vertical mesial section, with the lumbo-sacro-coccygeal curve, the inclination and shape of the symphysis, and the relations of the anatomical, obstetric, and diagonal diameters of the pelvic inlet, and also the sacro- and coccygo-pubic diameters of the outlet.

Of the three conjugates appearing in each vertical mesial section, I have emphasized the obstetric by drawing here a heavier line, and it is well to state at this point that we define the obstetric conjugate as the available antero-posterior diameter of the pelvic inlet.

50 EAST THIRTY-FOURTH STREET, NEW YORK.

OBSERVATIONS UPON  
THE FORMATION, STRUCTURE, FUNCTION, AND PATHOLOGY  
OF FISTULOUS PASSAGES OR SINUSES,  
ESPECIALLY THOSE WHICH  
CONSTITUTE ANAL AND RECTAL FISTULÆ,  
AND THE TENDENCY SOMETIMES  
OF SUCH TO SPONTANEOUS OBLITERATION AND CURE.

BY WILLIAM BODENHAMER, M.D., LL.D.,  
NEW ROCHELLE, N. Y.

It will be conceded that this particular subject, which the writer has selected for discussion on this occasion, has been till lately but little investigated by surgeons generally, either from not considering it of sufficient importance, or from not having had their attention especially and properly directed to it. It is a subject, however, in the estimation of the writer, that should not be neglected, but is well worthy of further consideration.

The writer in 1847, while in New Orleans, paid considerable attention to this subject, and promulgated his views upon it; since then he has, on one or two occasions, repeated the same; but, in consequence now of the

conflicting opinions of some recent authors regarding some parts of it, he feels called upon to resume again the further consideration of it.

Before entering fully upon the main features of the subject, the writer will endeavor to give the etymology, signification, and correct application of the word *fistula*, the importance of which will scarcely be called in question, especially when it is considered that there is perhaps no technical term in medicine more misapplied or indiscriminately used.

*Description and Definition.*—In describing any disease it is of the utmost importance to give, in the first place the etymology, signification, and application of its name. It is well known, however, that this self-evident truth is, singularly enough, almost always ignored by both authors and lecturers on the diseases *fistulæ* and *hæmorrhoids*. The Latin word *fistula* signifies a reed—hence a pipe, or a hollow cylinder. The ancient Latin authors called a catheter *fistula*, and a clyster pipe the same. Some recent authors erroneously, however, derive the word *fistula* from the Latin *fundo*, to pour out. But the Latin word *fistula*, in the opinion of the writer, finds its true prototype in the Greek word *σὺριγξ*, a pipe or flute, being derived from the Greek verb *σὺριγναι*, to whistle. The Greeks used the word *σὺριγξ* to represent the same disease which the Latins call *fistula*, as will be shown hereafter. The ancient flute or pipe was a hollow cylinder open at both ends; the modern flute or pipe is closed at the upper end. The name *fistula*, then, is very evidently taken from the similitude which the narrow cavity of a fistulous tube or tract has to that of a reed, pipe, or flute. This word, however, has, to a great extent, become disqualified for technical use by its numerous untechnical applications.

The term *fistula*, then, in pathology, simply denotes a narrow tube or conduit of variable length leading to a free surface from an abscess, cavity, or a normal canal, the seat of some local inflammation or irritation, and having a small orifice through which fluids or extraneous matters are discharged, greatly disproportionate generally to the extent of the morbid affection.

Paulus Ægineta says: "A *fistula* is a callous sinus, generally formed from an abscess, and derives its name from the pipes of reeds (*fistulæ*)." (*Libri Septem*, Græce et Latine, lib. iv, cap. xlix, folio, Basileæ, 1532.)

Celsus defines a *fistula* as follows: "Id nomen est ulceri alto angusto calloso." (*De Medicina*, lib. v, cap. xxviii, sec. 12.) Of all the ancients, Celsus has given the most minute, correct, and extensive description of *fistulæ*; indeed, there is nothing extant on the subject any more appropriate, even at the present time. Almost all the early writers defined the word *fistula* thus: "Sinus angustus callosus profundus; acri sanie diffluens."

In modern times, Dionis, the able French surgeon, defined the word *fistula* "Un ulcère profond et caverneux dont l'entrée est étroite et le fond plus large; avec issue d'un pus acre et virulent; et presque toujours ac-

compagné de callosités." (*Cours d'opérations de chirurgie*, édit. par M. De la Faye, tome i, p. 405, 8vo, Paris, 1782.)

The able Mr. Pott describes a fistula as follows: "The smallness of the orifice of the accidental canal; the hardness of its edges; its being found to be the outlet from a deep cavity; its discharging a thin, gleety, discolored kind of matter, attended with great induration of the surrounding parts—are all of them circumstances raising and confirming the idea of a true fistula." (*The Chirurgical Works*. Edited by Sir James Earle, vol. ii, p. 205, imp. 8vo, Philadelphia, 1819.)

The Latin term *sinus* is from the Greek *χάος*, a void, a cavity, and it and the term *fistula* are generally employed by many authors as synonymous, especially by many of the ancient writers; there is evidently, however, a difference, but in what it exactly consists is not so easily determined, in consequence of the numerous and various definitions and applications of it. A fistulous passage is narrow or of small calibre, and may have an internal as well as an external orifice, whereas a sinus is much wider, and has but one orifice, which is external. Medical lexicographers, however, usually define it a gulf, a cavity, or depression; or a long, hollow passage leading from an abscess, diseased bone, etc. But almost the same may be predicated of fistulous canals.

It may also be remarked here that the ancients, as well as some of the moderns in their definitions of fistula, include callosity as an essential element, but this is an error, as there are many cases of fistulæ unaccompanied by callus, as the writer has often observed, as well as have others. In the early stage there is scarcely ever any induration and thickening of the tissues in and around the fistulous tract; but in process of time these are brought about by frequent and long-continued irritating and inflammatory changes. This callosity in former times was considered by some to be of a scirrhous or cancerous nature, and subjected to very severe and injurious treatment. Some authors have said that the callous condition of fistulæ was produced by the ancient treatment of the fistulæ, which, say they, consisted of the introduction into the fistulous passages of highly irritating substances on tents or pledgets of lint, which constantly so excited and irritated the fistulæ as tended strongly to produce this callous state of the parts. But neither such treatment by the ancients nor by the moderns is the cause of this callosity. Such treatment, however, is much more applicable to some of the moderns than to that of the ancients. It is well known that more or less induration supervenes to inflammation, especially of the cellular tissue; and it is particularly observed in the callosities which follow the course of fistulæ in the ano-perineal region, which abounds in such tissue. The contraction and hardness in fistulous tracts take place very gradually, some considerable time after the acute inflammation, swelling, redness, heat, and pain in the

cellular membrane are entirely dissipated. These callosities, however, do not usually produce any other bad effect than that, perhaps, of retarding the cure of such fistulæ.

*The Improper Use of the Term Fistula.*—The term fistula is often misapplied, or is used in an indefinite or vague sense, thus giving a very inadequate idea of the true nature of the affection. Instead of simply denoting a pipelike or tubular sore, which is all that it does, or merely signifying the pipe, drain, or medium of conveying a fluid or extraneous matter to the surface, it is often applied to simple abscesses or to suppurating excavations, especially to all such in the vicinity of the anus. This departure, however, from its strict signification is doubtless caused, in this instance, by the fact that an abscess in the anal region most always precedes anal fistula, and that it is the initiative in the production of fistula. Abscess and fistula in the anal region stand in the relation of cause and effect, hence this complication is usually confounded, and the term fistula made to include too much. This distinction, however, is important, and must not be lost sight of, for the indications in the treatment of simple abscesses and fistulous tracts are essentially different. An anal abscess may or may not result in fistula, but it is liable, from various causes, sooner or later, to become fistulous, and when it does, the following is the process: After the pus in the first instance is evacuated, its parietes do not approximate and its cavity is not spontaneously obliterated, and it establishes in its walls one or more pipes or canals, which are fistulæ, and through which it discharges its secretions. An anal abscess may also become fistulous by its cavity gradually diminishing until it becomes itself a hollow cylinder or pipe. It is in this manner, then, that in time a definite organization is finally established, constituting a fistula. An anal abscess may, however, under favorable circumstances, terminate without becoming fistulous. If the artificial or the spontaneous opening of the abscess is made sufficiently large to completely empty it at once, the extent of its cavity diminishes rapidly and its parietes approximate, and we know, as in a wound, how they are simply agglutinated by means of the albumin and the fibrin, the blastema or blood plasma of the liquor sanguinis, which process either removes or prevents the action of the peculiar accidental tissue which lines abscesses and fistulous passages, and which will be described hereafter. It is therefore highly important, if not contraindicated, that an anal abscess should be opened in its most dependent part by a free incision just as soon as the slightest fluctuation can be detected in it.

An abscess, consequently, should not be called a fistula until it has in time acquired the characteristics plainly specified in the term.

The word fistula is also applied to many other affections which have no claim whatever to the appellation; for instance, it is indiscriminately applied to the diseases

of the lacrymal organs as well as to the following lesions: vesico-vaginal, urethro-vaginal, recto-vaginal, recto-vesical fistulæ, etc. But where, we ask, is the resemblance in them to the thing represented or signified by the term? These lesions or diseases are not fistulæ, but mere openings, breaches, or perforations; and their junction or communication is not effected by a pipe, tube, or canal. The great impropriety of denominating these affections fistulæ was demonstrated some years ago by MM. Jobert (de Lamballe) and Vidal (de Cassis). (*Annales de chirurgie*, mai, 1845.)

Mr. Bryant, the distinguished surgeon to Guy's Hospital, London, has, however, very cleverly disposed at once of the incongruity of the application of the term fistula to the lesions or affections just mentioned, as well as to all others of a similar nature, by making an entirely new definition of fistula, strictly conformable to the exigencies of the case. He says: "A fistula is an unnatural communication between a normal cavity or canal and the outside of the body or a second cavity or canal." (*The Practice of Surgery*, pp. 420, imp. 8vo, Philadelphia, 1873.)

It will be perceived, however, that the etymology and the signification of the word fistula are entirely ignored in Mr. Bryant's definition. In concluding this part of the subject the writer would only remark that the definition of the word fistula, as found in the hands of some recent authors, is furnished with very expansible qualities, so as to include or embrace that for which it was never intended. But these authors say that this definition should be employed or understood in a broad or comprehensive sense. Now, such authorities must know that if any definition or technical term of anything whatever is used in its broad or loose manner, it completely disqualifies it as a definition or as a technical term, and is utterly inconsistent and unreasonable.

*The Formation, Structure, and Pathology.*—The writer will now enter into a general consideration of the seat, development, organization, and properties of fistulæ.

It is known that fistulous canals may be developed in the different tissues of the body, but they are most frequently observed in the cellular membrane, and as this membrane is more thickly dispersed about the margin of the anus and in the perinæum, it is in these localities, therefore, that abscesses and fistulæ are most commonly developed. Indeed, the cellular tissue favors the formation and extension of these fistulous tracts, in consequence, doubtless, of the ready passage it affords to fluid matters, which often make their way rapidly in different directions in it with but little hindrance, it being the softest and most yielding of all the tissues of the body.

These fistulous passages, when developed in the anoperineal region, are generally single, but they often ramify at their extremities, usually communicating with each other with one or more external openings, and converging generally to but one internal rectal aperture. Their

direction is most frequently sinuous or tortuous, yet they are sometimes straight, and they often present numerous contractions and dilations in their course, and occasionally become insulated.

In the exploration of these often crooked passages the probe, if straight and inflexible, can not be made to follow the obliquities of them. The probe must be so flexible as to be capable of being bent or curved to such an extent previous to its introduction as to readily follow the track of the passage, and thus made, if possible, to discover the exact extent, the true bottom, or the internal opening, if any exists. These abnormal canals possess various degrees of sensibility; the introduction of the probe into them is sometimes productive of severe pain, while at other times the presence of the probe is readily tolerated.

The discharge from and through fistulous passages may present characteristics of pus, gleet, sero-purulent, sanguineo-serous, or mucous matter, but the discharge varies like the cause; sometimes it is white and consistent, often it is thin and flaky, at other times pure, and again it is mixed with the product of some natural secretion, according to the location of the fistula, the general health of the patient, the length of time the affection has subsisted, etc.

M. Dupuytren treats the subject of fistulous passages in a very able manner. After giving their formation and structure he says: "These accidental passages are formed at the expense of all the tissues in their immediate vicinity, taking the elements of their organization from them—hence the fibrous, nervous, mucous, and osseous tissues may all enter into their composition, according to the locality of the fistula. Mucous tissue, osseous substance, nerves, veins, and cellular tissue have been found in their organization, according to the parts in which they originated and through which they passed." (*Leçons orales de clinique chirurgicale*, tome ii, 8vo, Paris, 1834.)

*The Adventitious Tissue.*—The peculiar accidental tissue, previously alluded to, which lines the internal surface of these abnormal passages bears some analogy, by its organization, properties, and functions, to the natural mucous membrane. Indeed, this peculiar tissue, which is neither a pseudo-membrane nor a mucous membrane, commences to be organized in all abscesses at a certain stage, just before they spontaneously open or are lanced, and it completely circumscribes the purulent collection in them; and should any of such abscesses subsequently result in fistulous passages, these will be found lined with the same kind of tissue.

Mr. John Hunter was the first to call attention to the existence of a peculiar tissue lining fistulous passages, apparently like mucous membrane. He says: "The internal surface of fistulæ has an appearance similar to that of a secretory membrane, and may be compared to the urethra." And again he says: "I believe that a deep wound, such as that from a gunshot, on pro-

ceeding to suppuration and forming a fistulous canal, becomes in some degree analogous to an excretory canal, having the power of producing peristaltic motions from the bottom to the external opening." (*A Treatise on the Blood, Inflammation, and Gunshot Wounds*, 4to, London, 1794.)

M. Dupuytren especially calls attention to the apparently mucous membrane which lines the inner surface of the fistulous canals. He considered this peculiar tissue to be a real mucous membrane, similar to the normal mucous tissue, and differing from it only by the absence of follicles and a layer of epidermis. M. Breschet has also produced an able article upon this subject, entitled *General Reflections on Fistulæ*, and on the Formation of an Accidental Membrane in their Course. Of this membrane he remarks: "The organic elements of the adventitious membrane of fistulæ have the greatest analogy with those of the mucous membranes. This membrane is separated from the surrounding parts by a greater or less extent of cellular tissue, which may be termed submucous, and it contains a portion of that structure in its composition, as may be demonstrated by maceration." (*Journal universel des sciences médicales de Paris*, juin, 1818.)

No regularly developed anal fistula is destitute of this adventitious tissue lining its internal surface; it is indeed essential to the formation of the disease, and in simple cases it is often the only organic change existing. According to M. Dupuytren and M. Breschet, this tissue, in proportion as it acquires age, undergoes considerable changes, becoming more and more like mucous membrane, and at a late period of its existence it will be found red, and its redness reveals many small blood-vessels which terminate on its surface by exhalants, the existence of which is evident by the secretion of fluids; and also, like the mucous membrane, it will be found soft and villous, and if examined with a glass the villousities may be distinguished. (*Op. cit.*)

The few cases, however, in which the writer himself carefully examined this tissue, which were all of recent origin, however, he found it much thinner, more delicate, and of a paler red color than the normal mucous membrane; neither was it as soft, velvety, and firm, and, when examined with the glass, he found its surface slightly tomentose and its texture filamentous, and the blood-vessels and the villi were quite easily discernible. This tissue is evidently a low formation of the cellular membrane, and is of such a feeble character as to be easily removed by curetting or by the mildest escharotics, as the writer has often demonstrated.

Although this peculiar tissue possesses several strong traits of resemblance to the natural mucous membrane, yet the difference between them is so remarkable that their perfect identity can by no means be established or admitted. It may be said, however, that it is more analogous, perhaps, to the mucous membrane than to any other species of structure. M. Dupuytren considers this

tissue to be a real mucous membrane, but admits that it is destitute of follicles and a layer of epidermis. This, however, is no inconsiderable difference, as it lacks the cuticle to protect it, and those important glandular bodies, the mucous follicles, which are dispersed throughout the mucous membrane and secrete a viscid fluid for the lubrication of its surface. These, however, are not the only differences of organization between the accidental tissue and the natural mucous membrane; the former is known sometimes to be spontaneously effaced, and the fistulous passage it lines is obliterated; or it may be easily displaced artificially with the same result. This, under similar circumstances, however, can not be said of the latter, inasmuch as such an occurrence is rarely or never observed. For instance, the mucous membrane of the intestinal canal, below an artificial anus, either in the groin or in the loin, remains normal and continues to secrete mucus, and the canal itself, too, remains pervious, although all the fæcal matters are diverted from it and no spontaneous obliteration ever occurs.

This peculiar tissue or inclosing cyst of abscesses, and which also lines fistulæ, has been called pseudo-membrane by some, but it is evidently not so, as can be easily demonstrated. A false membrane is known to be an exudation of a fibrinous character, chiefly from the capillaries of inflamed mucous membranes, and is deposited in layers on their surface, as in croup, diphtheria, etc., and is analogous to the exudation on serous membranes. Indeed, this accidental tissue is neither a false membrane nor a false nor a true mucous membrane, but it is *sui generis*. The learned Lobstein has denominated it "tissu pyogénique." (*Traité d'anatomie pathologique*, folio, Paris, 1829.) He believed that the function of this tissue was really to generate or secrete pus, thus agreeing with Mr. Hunter, who, as has been shown, was the first to call attention to this tissue, and to suggest the idea that mucus or pus was its true secretion. But the writer has previously shown, however, that in abscesses this same kind of tissue, which lines and completely encircles them, is organized subsequently to the generation or the secretion of the pus; consequently it could not have had anything whatever to do with the process of pus generation. Indeed, it would be much more plausible to suppose that this tissue was designed as a wall or barrier thrown around the abscess, to confine it and its contents within bounds, and thus to prevent their spreading into the loose cellular tissue of the anal region, than to believe that its function was merely to develop or secrete pus. It, however, is not more of a pus-secreting tissue than are the mucous membranes themselves, which is certainly not their function; yet, under inflammation, an ichorous fluid from their capillaries is frequently thrown out, which in reality, sooner or later, becomes muco-purulent or actual pus, without the least appearance of a solution of continuity; consequently, can both the accidental and the mucous tissues be considered truly pyogenic?

It is also said by some authors that this accidental tissue is not only a pus-secreting, but an absorbing agent also; yet it would seem that the instances must be few indeed in which pus would find its way into the circulation from abscesses and fistulæ through the medium alone of this tissue.

But, after all that has been said and observed of this tissue, it must be admitted that there is much yet to be learned of a definite and positive character in relation to it; and it is only by means of new and further researches that the true nature, functions, and characteristics of it can be precisely determined.

*The Importance of Early Treatment.*—The writer, at the commencement of this discussion, did not contemplate saying anything upon the treatment of fistulæ, but confine himself strictly to the text; but, upon reflection, he thought it best on this occasion to make a few brief remarks upon the treatment of simple or superficial anal fistulæ, reserving for a future article the treatment in full of anal and rectal fistulæ.

It is not only important to prevent an anal abscess from becoming fistulous, but it is equally important, after fistulous passages have formed, to treat them radically at once, before their parietes and their internal lining tissue become perfectly organized by time, and thus become involved in serious pathological changes. It is here that conservative surgery may especially be of essential service in the early treatment of simple and superficial cases of anal and rectal fistulæ, inasmuch as most all such cases at an early period may be successfully treated without division or excision of the morbid parts. In early childhood it is remarkable with what rapidity fistulous tracts or sinuses coalesce and get well by the mildest treatment. The writer has successfully treated ten young children of anal fistula during a practice of fifty-seven years; in all such cases the knife is especially contraindicated, in consequence of the frequent fluid fecal passages of early childhood.

The late and able surgeon, Dr. Gibson, says that "an opinion generally prevails that every fistula in ano requires an operation. There can not be a greater mistake. So far from it, almost every sinus, I am inclined to think, in a patient tolerably healthy otherwise, might be healed if attended to in the commencement and judiciously managed. Nothing will contribute more to this end than absolute rest, simple dressings, moderate diet, and mild laxatives. I have known a fistula, protracted and kept open for months while the patient walked about, healed in a week by perfect quietude and the horizontal position." (*Institutes and Practice of Surgery*, vol. ii, p. 152, imp. 8vo, Philadelphia, 1850.)

M. Preschet says: "By a judicious use of proper measures, we may almost always spare the fistulous patient an operation, which, although generally exempt from serious danger, is nevertheless productive of more or less severe suffering, and often gives rise to very unpleasant consequences." (*Op. cit.*)

The writer would here remark, however, that it must be distinctly understood that in all complicated cases of anal and rectal fistulæ, in which a large amount of the soft parts in the anal region, including sometimes the whole of one or both buttocks, is involved, attended with deeply burrowing sinuses and more or less external openings, no confidence whatever can be placed in any other treatment than in that which contemplates the complete division of all the morbid passages, both external and internal, by either the ligature or the knife. When a deep fistulous tract is divided by the knife, to aid in insuring success it is essential that the accidental tissue should be removed either by curetting or by excision, and the wound closed by suture. By the use of the ligature, however, this proceeding is entirely obviated, as it completely destroys the adventitious tissue and the callosity by the adhesive inflammation which it induces and keeps up, as it gradually divides the walls of the morbid tract, not by cutting, but by a process of ulceration and suppuration. But it should be remembered that, in the treatment of either the simple or the complicated form of fistulæ, much indeed depends upon the skill, the judgment, the experience, and the prudence of the surgeon to direct the application of the various and numerous remedial measures according to the exigencies of each individual case.

*Indications in the Treatment of Simple Fistulæ.*—The chief indication in the treatment of simple fistulæ in patients otherwise healthy is to destroy the accidental tissue which lines their internal surface, which, when accomplished, modifies the condition of their parietes, and, together with dilating or enlarging the orifices of the passages, and complete drainage, decidedly favors granulation, cicatrization, obliteration, and cure. The chief indication may be effected by means of various escharotics, some in the form of fluids, as injections, and others in the potential form, as applications. Some of the fluids which have been used successfully in some of such cases by the writer, as well as by others, are the tincture of iodine, or, what is preferable, a solution of iodine in ether, being more volatile, escapes more rapidly, leaving the parietes of the fistulous tract in contact with the pure iodine; a strong solution of the nitrate of silver, and also the following preparations:

R̄ Acidi carbolic.	gr. xxx;
Glycerini	℥ ij;
Aq. destillatæ.	℥ iv.
M. Fiat solutio.	
R̄ Hydrarg. chloridi mitis.	gr. xxx;
Hydrarg. chloridi corrosivi.	gr. j;
Mel. despumati.	℥ j;
Aq. destillatæ.	℥ ij.
M. Fiat mistura.	

To suit some delicate cases these injections may be slightly diluted, and the pain, if any, resulting from their use, may generally be mitigated by the application of hot fomentations or poultices. A few injections at intervals of a day or two may be all that will be required.

A number of other escharotic solutions suitable for injections in such simple cases could here be given, for such abound and are known, and will suggest themselves to practitioners generally.

With regard to the application of some of the escharotics in the potential form, the writer has treated successfully quite a number of cases of simple and superficial anal and rectal fistulæ, in which there existed one or more straight or slightly curved fistulous tracts, by means of probes of silver or copper of different sizes and coated with caustic. The silver probe may be coated with the nitrate of silver by dipping it several times in the fused salt and introduced into the whole length of the fistulous passage; or the copper probe may be coated with the nitrate of copper by dipping it in nitric acid, and inserted like the former. A choice can thus be made between the nitrate of silver and the nitrate of copper. The writer has had the most success with the latter. The former was the suggestion of Sir Benjamin Brodie, and the latter was that of Mr. Evans, of London. When a silver and a copper probe are dipped in nitric acid and introduced together into a fistulous passage, the caustic effect is greatly increased, and if suffered to remain in too long would destroy the tissues with which they were in contact. This is the effect of the galvanic action set up by the contact of the copper and the silver probes with the acid acting upon them.

The writer is well aware, however, that even all such conservative measures as have just been considered for the treatment of the simple or superficial form of anal and rectal fistulæ are, except the knife, denounced in unmeasured terms by a few newly fledged rectal specialists of the school of "official" surgery as unsurgical, unscientific, and unworthy of their profound attention. These upstart and would-be authorities attempt thus to degrade and depreciate the persons, the experience, and the treatment, in this respect, of numerous eminent men in the profession, whose genius is as brilliant as the face of these their detractors is brazen.

*The Spontaneous or Natural Cure of Fistulæ.*—The natural or spontaneous cures of anal and rectal fistulæ are not of frequent occurrence, yet occasionally isolated cases do present themselves in which a fistulous passage or passages will close and become obliterated without any medical or surgical interference; this event often occurs even when the general health of the patient is seriously affected otherwise. Cases of this kind have long since been reported by such eminent men as Pott, Ribes, Velpeau, and Allingham, which emphatically demonstrate the fact that Nature sometimes spontaneously effects cures of fistulous canals. This subject has, perhaps, not been sufficiently reflected upon by surgeons generally, for numerous circumstances point to the fact that Nature herself attempts to cure fistulæ, and they who ignore Nature's efforts in this respect lose some valuable points in their indications of the cure of fistulæ by any method. In confirmation of this very fact, the

great English surgeon, Mr. Pott—who, like Celsus, has given us so much valuable information upon the subject of fistula in ano, and who in his day effected so complete a revolution in the then barbarous methods of operating in this disease—says, when speaking of the tendency of fistulous passages to spontaneous cure: "They may not always become perfectly closed and heal, but the aim and conduct of Nature are not, therefore, the less evident, or the hint which art ought to borrow from her the less palpable." (*Op. cit.*, p. 218.)

The following is, perhaps, the *modus operandi*, then, in which a spontaneous or natural cure of fistulous canals may take place: The composition of such canals is contractile, like all other tissues of the body, and their lining membrane, being accidental and not mucous, is consequently not liable of itself to prevent the union of the parietes of these passages; therefore, just as soon as they, from some new action in them, begin gradually to cease giving exit to their accustomed discharge, or that which caused them, their cavities in the same ratio begin consequently to contract and become capillary, union and adhesion of their parietes take place, and finally they are changed into a dense fibro-cellular mass resembling a cord, which may sooner or later altogether disappear.

A case of this very kind came under the observation of the writer at New Orleans in March, 1847.

Mr. P., of Columbia, South Carolina, on a visit to New Orleans, brought with him his body-servant, George, a rather delicate mulatto about twenty-five years of age, who soon after his arrival contracted a severe cold, which rapidly terminated in pleuro-pneumonia and death. Two years previously this man had a complete fistula in ano, which in less than a year closed and healed without any medical or surgical treatment whatever. An autopsy was permitted the writer, who could distinctly feel the cordlike cicatrix, the remains of the fistulous tract, which he completely removed. It measured three inches and a half in length, and its parietes were firmly united and had precisely the appearance and the feel of a cord.

Since then the writer has observed five similar cases. Mr. Allingham has reported twelve cases of spontaneous cures of anal and rectal fistulæ. (*Fistula, Hemorrhoids, etc.*, p. 16, 8vo, London, 1871.)

The writer received the following highly interesting letter from John E. Weaver, M. D., of Rochester, N. Y., dated March 9, 1891, which will explain itself:

"Dr. W. Bodenhamer:

"DEAR SIR: I have just been reading in the *Medical Record* of February 28, 1891, your remarks upon the spontaneous cure of fistulæ. As your record of cases seems small, I thought you might wish to add to it my own case.

"While practising my profession in Roxbury (Boston), Massachusetts, in the winters of 1877 and 1889, I took several severe colds, had pleurisy, a severe cough, with purulent expectoration, torpid liver, constipation, night sweats, loss of appetite and flesh, followed by an anal fistula which was very painful and discharged

freely for several months. All the local treatment it had was free bathing. General tonics and fresh-air exercise did the rest. The fistula closed, I believe, in about a year, and has remained closed since, etc."

The writer will now conclude by repeating that a knowledge of the phenomena relative to the spontaneous cure of fistulæ is of considerable importance to the successful treatment of their various kinds by whatever method employed, and should be an object of interest and consideration in the indications of their treatment and cure.

Now, should any one accuse the writer of too much detail in this article, he must plead the importance of the subject, and the neglect with which it has been treated by most authors. He has introduced nothing which did not appear necessary to display the existing state of our knowledge of these facts, and nothing that will not tend to elucidate the pathological remarks contained in the article.

## ATLANTIC CITY IN THE AUTUMN.

By JOSEPH F. EDWARDS, A.M., M.D.,

ATLANTIC CITY, N. J.,

FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA;

MEMBER OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY;

EX-MEMBER OF THE STATE BOARD OF HEALTH OF PENNSYLVANIA;

FOREIGN ASSOCIATE MEMBER OF THE FRENCH SOCIETY OF HYGIENE, ETC.

It was in 1859 that the late distinguished Dr. Samuel Jackson, of Philadelphia, then professor of the theory and practice of medicine in the University of Pennsylvania, made the statement that he considered the atmospheric condition of Atlantic City one of the most peculiar in the country, and he ventured the prediction that it would in time become available in the treatment of many diseases.

In 1873 the late Dr. William V. Keating, of Philadelphia, after visiting and studying all the famous health resorts of Europe, wrote: "What a precious boon will it be to the invalids of our country if, without the necessity of exposing themselves to a long sea voyage, they can find in their own native land all the variations of climate and hygienic conditions conducive to their restoration to health, or to the amelioration of their sufferings!"

These predictions and anticipations have been realized to an extent scarcely thought possible by their authors, until, in 1896, the pre-eminence of Atlantic City as a health preserver and health restorer is everywhere recognized and conceded. Many theories and speculations have been from time to time advanced to account for the truly marvelous effects of this place, but, to my way of thinking, after a residence of some years, the results produced are due to a combination of natural and artificial conditions not to be found in any other spot on earth. Nature has done much, and what she has left undone art has completed; for even the most beneficent efforts of Nature will be to an extent nulli-

fied if not supplemented, perfected, and maintained by the co-operation of art.

Let us for a moment consider the geographical situation of Atlantic City: Situated on a strip of sand some eight miles long and possibly three quarters of a mile wide, the Atlantic Ocean in front and five miles of meadow land in the rear, it reminds one of a ship at sea, this fancy being intensified by the fact that many times during the course of the year the meadow land in the rear is covered by salt water to a depth of four feet or more, at which times Atlantic City is practically an island "five miles out at sea."

Thus Nature has surrounded this city with an "ocean atmosphere," so to speak, very unfavorable to the growth of pathogenic bacteria, as is demonstrated by the almost complete absence of zymotic diseases among the inhabitants. During a practice of five years in Atlantic City I have seen only one case of scarlet fever, four cases of typhoid fever, a very few cases of measles, no diphtheria, and no malarial disease, and the records of the health office demonstrate that the experience of other physicians is on a par with mine.

This remarkable exemption of the atmosphere from pathogenic bacteria makes Atlantic City a most favorable locality for operative procedures, wounds healing with unusual rapidity and freedom from suppuration, so that surgeons are not only commencing to bring their patients here to prepare them for operation, but are actually performing the operations here, in an atmosphere that is naturally aseptic. Here, then, we have the first requisite of health, an atmosphere free from the causes of disease.

It is a fact demonstrated by a large number of cases in my own experience that sufferers from hay fever enjoy more freedom from this distressing complaint here than at any other place, so that year by year the colony of sufferers from this affection is rapidly increasing. Contradictory as it may at first seem to say that the seashore is suited to rheumatic patients, yet experience convinces me that they do well here, particularly in the fall of the year. This fact is probably attributable to the abundance of sunshine and the singular absence of foggy weather that characterize Atlantic City during the fall, for from the official records of the weather bureau I learn that during the months of October, November, and December for the five years 1890-'94 (inclusive), while there were sixty-three foggy days in New York city, Atlantic City had only five; with one hundred and fifty-one cloudless days here as against only a hundred and sixteen in New York.

The very great importance of sunshine as a therapeutic agent can not be overestimated, and, to my way of thinking, its plenitude here is one of the most effective remedial agencies of the locality. It really seems as though the sun shone here with an almost unequalled warmth, generosity, and brilliancy; and when it disappears in the west at the close of day, it leaves

behind an influence that tempers and moderates the evening atmosphere, so that we do not have here the evening chilliness and dampness so marked and so detrimental at the health resorts along the Mediterranean.

The atmosphere of Atlantic City might be characterized as a "stimulant sedative," if I may be allowed the Hibernianism and a few words of explanation. The visitor seems perfectly content to eat, walk, and sleep. The appetite improves at once; the digestive and assimilative vigor grows apace with the appetite; the glorious board walk along the ocean front invites walking, which is indulged in by all, and every one is always ready for sleep.

As might be supposed, such an atmospheric combination works wonders in functional nervous disorders, offering, as it does, a stimulant to the physical and a sedative to the nervous system.

Voluntary laziness—mental quietude and inaction, without chafing and fretting thereat, so desirable in nervous disorders, and so difficult to secure—is the natural result of the influence of this atmosphere.

Without going into tiresome statistics it is sufficient to say that official records prove that Atlantic City is several degrees warmer in winter and cooler in summer than either New York or Philadelphia, which is accounted for by the fact that the prevailing winds are from the southwest, while those of both New York and Philadelphia are from the northwest. Snow rarely falls here, and when it does it is gone and the streets are dry in a few hours, owing to the potency of the sun and the porous, sandy soil. A great feature of this atmosphere, one that has been more commented upon than any other, is its remarkable dryness, concerning which Dr. William V. Keating wrote: "This remarkable dryness of climate is the characteristic of Atlantic City, which affords relief and cure to all cases of rheumatic fever and arthritis, even in the most acute stages. I know of many instances in which invalids, after having recourse, without benefit, to the various mineral waters and baths in the country, have there been entirely cured."

"To another class of cases also I am convinced," writes Dr. Keating, "that Atlantic City offers relief, if not positive cure, which can not be obtained on any other portion of our seacoast. I allude to those trying and refractory cases of chronic bronchitis, laryngitis, incipient tuberculosis, and scrofula. It is difficult to estimate the immense advantages resulting to invalids suffering from pulmonary and scrofulous affections, being able to obtain all the benefits accruing from the invigoration and improved digestion of a seaside residence, without the usual pernicious accompaniment of excessive dampness, which relaxes the system and predisposes to a general catarrhal condition."

This testimony of Dr. Keating has been corroborated by many eminent medical men, among whom I might name Dr. Lawrence Turnbull, Dr. Thomas J. Yarrow,

Dr. Thomas G. Morton, Dr. James Darrach, Dr. John H. Packard, Dr. D. Murray Cheston, Dr. Ellwood Wilson, Dr. R. J. Levis, Dr. James J. Levick, and Professor J. M. Da Costa, M.D. Dr. Ellwood Wilson wrote: "During the *winter months* I regard it as a very favorable locality for consumptive patients."

Dr. William Pepper, of Philadelphia, is particularly emphatic in expressing his belief that the climate of Atlantic City acts powerfully, in most cases, as a dry and bracing climate. In incipient phthisis, and even when the disease had advanced to the second stage, he has noted great and permanent benefit. My own convictions, as the result of experience, observation, and interchange of thought, are that when we speak of the "dry, bracing, invigorating, aseptic atmosphere" of Atlantic City, we have the whole question in a nutshell. The testimony of all physicians who have written upon the subject is that it works marvelous results in all diseased or disordered conditions characterized by exhaustion, lowered vitality, lack of tone; hence, that a sojourn here is particularly indicated in all such conditions, in protracted convalescence from acute diseases, and as a preparation for all serious operations.

It is evident from what has been already said that Nature has done much for this place. What she has not done, man has. Mental diversion is a recognized therapeutic agency of immense potency, and Atlantic City offers mental diversion to minds of any and every type. It is a miniature metropolis, lacking no luxury or convenience, wherein a man may be saintly or diabolical, as the spirit moves him.

It is a health resort devoid of all the usual mournful and depressing accompaniments of such places; it is truly a "city of health and pleasure." So long as one behaves himself with decency, he can do about what he pleases; he has churches and saloons and theatres and boats, and amusements of all kinds; he has a magnificent board walk, forty feet wide and four miles long; and last, but by no means least, he has hotels equal in comfort and elegance to any in the world.

Atlantic City is the best-known health resort in the United States, and is full of visitors from all parts of the country for nine months of the year. But, for some unaccountable reason, it is not sought, as it should be, during the most desirable season of the year—during the autumn and very early winter. Words can not paint the glory of this climate in October, November, and December, and it is to remind physicians of this garden-spot, so close to home, so accessible and so inviting, that this article has been written.

A very convincing proof of the peculiar merits of Atlantic City as a health resort is to be found in its almost magical growth during the last twenty-five years. In 1871 the resident population was 1,160, in 1896 it is 21,000—an increase of twenty fold. This growth is neither accidental nor spasmodic; we have no commercial industries save those dependent upon our visiting

population; this steady growth of resident population is but an index of the steady growth of the reputation of Atlantic City as a health resort; the physicians of the country have made this place what it is because they have been ready to recognize and commend its merits, but they are not yet fully alive to the superior attractions of the place in the autumn.

We have a rapidly growing leisure class in this country, whose wealth relieves them from the necessity of close application to business, yet whose interests call for personal supervision; for such, Atlantic City offers an ideal fall and winter home, possessing all the advantages of European health resorts, yet within three hours of New York city.

No. 1625 PACIFIC AVENUE.

## PRELIMINARY NOTE ON BLENNOSTASINE.

By WALTER F. CHAPPELL, M.D.,

SURGEON TO THE MANHATTAN EYE, EAR, AND THROAT HOSPITAL.

BLENNOSTASINE, although somewhat analogous to quinine, is without many of its unpleasant qualities. The drying or blennostatic effect of this remedy has suggested the name, which is more convenient than the chemical designation.

The compound is a derivative of one of the cinchona-bark alkaloids and is a solid substance which crystallizes from dilute solutions in large, prismatic crystals, or from concentrated solutions in the form of small, needle-shaped crystals, very soluble in water and quite as bitter as quinine.

Blennostasine may be administered in capsule form, when combinations are required; but for many reasons one-grain gelatin-coated pills are preferable. The dose ranges from one to four grains or more every hour, according to the effect desired. It has a marked contractile effect on the vasomotor system of the upper respiratory tract, and, being non-toxic, is especially valuable as a substitute for belladonna, atropine, and similar drugs in hay fever, acute influenza, and rhinitis; also in intermittent rhinorrhœa, laryngorrhœa, and bronchorrhœa. It has a powerful sedative influence on the brain and spinal cord, and markedly diminishes reflex movements.

During the past two years the writer has employed many of the alkaloidal salts from cinchona in hay fever with only partial success, but during the past season blennostasine has replaced these and other internal remedies with gratifying results—in fact, all hay-fever patients who have taken the remedy have been promptly relieved, and, though a recurrence of the symptoms next year may not be prevented, the usual attack may be aborted if the treatment is begun sufficiently early.

Quinine is very popular with the laity for colds in the head and influenza, but it only modifies the symptoms and is rarely curative. The salt blennostasine has medi-

cinal properties superior to those of quinine for arresting supersecretion, and if given frequently and in sufficient quantities will almost invariably arrest the sneezing and the mucous discharges of ordinary influenzal colds.

Hyperæsthetic conditions of the nasal mucous membranes are very favorably influenced by it, and one case of spasm of the glottis, which had become very alarming, owing to the quantities of mucus which collected at night, was completely controlled by this drug.

7 EAST FIFTY-FIFTH STREET, November 6, 1896.

## A SHORT REVIEW OF MECHANO-THERAPY IN CONNECTION WITH OBSTETRICS.

By AXEL V. GRAFSTROM, B. Sc., M. D.

By mechano-therapy we understand the mode of treating diseases by movements. It is a science both in theory and in practice. Founded on purely scientific researches, discoveries, and facts, its path runs parallel and in close contact with physiology, anatomy, and pathology.

We should carefully distinguish between mechano-therapy and educational gymnastics or physical education. The former is a purely remedial agent. It aids Nature in her battle against disease. The latter assists Nature in the development of a fine physique. Its mission is to create a healthy body as a dwelling for a healthy soul, rather than to restore to health a body diseased.

The movements may be either active or passive. If the movement is executed by the patient's own will and power it is called active. A passive movement is performed either with or on some part of the patient's body by a will and power other than the patient's.

The principal postures in which we place the patient when performing a movement are the standing, sitting, and lying postures. These positions may again be subdivided into more complicated ones.

By medical gymnastics we understand that branch of mechano-therapy which deals with active and passive movements of different joints of the body. These movements can be: flexion, extension, abduction, adduction, rotation, and circumduction. Massage is a series of passive movements executed on the patient's body in a variety of ways, and constitutes the other variety of mechano-therapy. These passive movements are: friction, kneading, percussion, stretching, pressure, vibration, and stroking.

Although a science in itself, we must always bear in mind that mechano-therapy is only a remedial agent to be used by the physician, surgeon, or specialist as a part of the general treatment of a disease. Any member of the medical profession who has had a large experience in either private or public practice will certainly recognize the importance of mechano-therapy in connection with obstetrics. In order to simplify the matter

we will review medical gymnastics and massage during the three different periods: pregnancy, labor, and the puerperal state.

**I. PREGNANCY.**—In women of sedentary and indolent habits, and who at the same time are high livers, general massage with medical gymnastics will prove beneficial as an aid to the overworked digestive organs, as a stimulant to the congested liver, and as a substitute for exercise. The treatment should be given in bed either daily, or four or five times weekly.

**II. Degeneration, neurasthenia, and muscular relaxation** are generally to be found both in women who are reared among the luxuries of civilization and move in "society," and in members of the "*demimonde*." Late hours, all kinds of excitement and dissipation have made them quite "*blasées*." A tardy and painful labor must be expected among this class. Mechano-therapy, given during pregnancy, will to some extent counteract the anomalies of the expellent forces in such cases, and should be so directed as to strengthen the abdominal muscles and to make the ligaments of the pelvis more elastic; also so as to be a sedative for the nervous system. The treatment should be given in bed, and for three quarters of an hour daily.

**III. Occasionally** we meet women with an excellent physique, who, during pregnancy and without suffering from any disease, lose flesh and strength. Such a woman grows emaciated and anæmic, and after a difficult and abnormal labor gives birth to a very large child. Her pelvis may be entirely normal. In such cases, and having the experience of a previous labor to govern us, a course of mechano-therapy will often improve the situation. The object of the treatment should be to increase the action of the organs of nutrition and to carry the increased nutrition toward the mother's muscular system; that is, from within outward. By this the development of the fetus will be retarded and after a normal and comparatively easy labor a normal-sized child will be born.

**IV. In nausea and vomiting of pregnancy** a course of massage and medical gymnastics will often be beneficial.

**V. The digital stretching or dilatation of the os externum and cervix** in cases of hyperemesis during pregnancy is only an act of massage.

The question will now arise, How close up to labor do we dare to extend the treatment of mechano-therapy? The answer must be: The attending physician should be the judge in each case. Cases have been reported where the treatment was carried out daily up to the first stage of labor.

**LABOR.**—*First Stage.*—In this stage labor becomes pathological when the pains are defective on account of their short duration. When everything else is normal and labor far advanced, the object of the treatment should be to make the pains longer and more expulsive in character; it is to produce effective uterine

contractions. Massage, properly executed, will often be of great service. It should be performed in the following order: friction of the fundus, vibration of the fundus, palmar stroking of the lateral sides of the uterus from above downward, all through the abdominal wall.

*Second Stage.*—When the rotation of the head is completed and the pains are weak and irregular, and the only resistance to be overcome is that of the soft parts, the time for the forcible expulsion is at hand. This performance is only a variety of massage.

*Third Stage.*—Undoubtedly, the dangers of this stage are best overcome by massage. It should be performed in the following way: friction of the fundus, kneading of the fundus, and during the acme of a contraction palmar pressure of the uterus from above downward, together with some slight vibration. These procedures should be carefully executed through the abdominal coverings until the placenta is expressed, which is usually effected during the third or fourth pain.

After delivery of the placenta massage is again indicated. Now it consists of gentle friction, kneading, and pressure of fundus until contraction and retraction of the uterus are accomplished. These manipulations are to be repeated when the uterus shows a tendency to relax.

**I. THE PUERPERAL STATE.**—In cases of *phlegmasia alba dolens* mechano-therapy is exceedingly useful. The treatment should commence when the tenderness subsides and the leg begins to pit on pressure. The different manipulations should be: friction, kneading, palmar percussion, vibration, and stroking, together with passive and active movements.

**II. CAKED BREAST AND MASTITIS.**—Caked breasts are promptly relieved by massage. Parenchymatous inflammation following a caked breast can also be successfully treated in this manner. Even in cases of mastitis, where pus already has been formed, it can be evacuated by skillful massage. The different manœuvres should be done in the following order: friction, digital kneading, palmar pressure and vibration, digital stroking. These manipulations should be directed from the base of the breast to the nipple. Massage is contraindicated when there is a gradual rise of temperature, dull pain in the breast, redness and œdema of the skin, enlargement and tenderness of the axillary glands—in short, all symptoms of interstitial mastitis.

**III. SUBINVOLUTION.**—Mechano-therapy plays a prominent rôle in the treatment of this abnormal condition of the uterus. It may be caused by chronic pulmonary, cardiac, or hepatic diseases, by chronic constipation, by rising too soon after parturition, by displacements of the uterus, by retained secundines, by a lacerated cervix or perinæum, or by any uterine or pelvic inflammatory process. The accepted rule is: first, to treat the cause, if possible, and then to employ mechano-therapy in order to relieve the congestion.

IV. The excessive enlargement of the breasts and great relaxation of the abdominal muscles so often noticed after labor may be treated with advantage by massage and medical gymnastics.

V. During this period mechano-therapy has often been successfully employed to correct displacements of the uterus.

VI. A symptomatic, if not an anatomical, cure will be effected by this treatment in cases of movable kidneys which during labor have become further displaced and produce distressing symptoms.

Medical gymnastics and general massage can without danger begin two weeks after labor. Pelvic or direct uterine massage should not be given before the seventh week.

### ANOTHER INTERESTING CASE OF GONORRHOEA IN THE YOUNG.

By J. DOUGLAS WESTERVELT, JR., M. D.,

ALICE, TEXAS.

SURGEON TO THE SAN ANTONIO AND ARANSAS PASS  
AND TEXAS-MEXICAN RAILWAYS;

MEMBER OF THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES,  
ETC.

I HAVE read with interest the articles by Dr. Cox, of Galveston, and Dr. Lofton, of Atlanta, on gonorrhoea, associated with epididymitis, in children, but I can report a case I think more interesting and decidedly more unusual than any of those mentioned—that of a child five years of age and of Mexican parentage. While preparing to amputate his leg (on account of a railroad accident) on the 23d of September last, I found, to my amazement, that he was the diminutive sufferer from well-defined gonorrhoeal epididymitis, accompanied with chancroid and bubo of the left groin.

I could find no cause to which this case could be attributable, save that of the child's being tampered with by questionable characters of his own nationality. This disease is undoubtedly more prevalent among Mexicans of the lower class than in any other race of people with whom I have had any experience.

### Therapeutical Notes.

**Eucalyptus as an Antidote to Strychnine.**—It appears by an abstract from an Italian journal (*British Medical Journal*, August 29, 1896; *Edinburgh Medical Journal*, November, 1896) that Muscecchi has found experimentally that a decoction of eucalyptus mitigates the poisonous action of strychnine very decidedly. He therefore recommends its use for washing out the stomach in cases of strychnine poisoning.

**Hæmol Hydrargyroidide in the Treatment of Advanced Syphilis.**—Kobert (*Centralblatt für Nervenheilkunde und Psychiatrie*, May, 1896; *Fortschritte der Medizin*, November 1, 1896) recommends this preparation, said to contain thirteen per cent. of mercury and twenty-eight per cent. of iodine, in combination with blood pigment, especially in cases of advanced syphilis in which the internal administration of mercury is indicated. The particular advantages of the compound are said to be that it is perfectly unirritating to the mucous membranes, that it passes through the stomach without being dissolved, and that, together with the specific effect of iodine and mercury, it exerts a mild chalybeate action. The formula is as follows:

℞ Hæmol hydrargyroidide..... 150 grains;  
Opium..... 15 “  
Glycerin ointment..... a sufficiency.

Mix and divide into a hundred pills, of which there may be given at first one, gradually increased to four, three times a day.

**A Wash for Incipient Baldness.**—The *Therapeutische Wochenschrift* for November 8th gives the following formula:

℞ Salicylic acid..... 1 part;  
Alcohol, )  
Glycerin, ) each..... 20 parts;  
Tincture of soap, )  
Peruvian balsam..... 6 “  
Cologne water..... 14 “

M. Digest for fourteen days, and filter. The scalp is to be rubbed with the wash daily.

**The Treatment of Acute Coryza.**—Dr. Georg Rosenfeld, of Breslau (*Allgemeine medicinische Central-Zeitung*, 1896, No. 88; *Therapeutische Wochenschrift*, November 8, 1896), uses a four-per-cent. solution of nitrate of silver with which he swabs the nose thoroughly three times within an hour. After from three to twenty hours he repeats the application. This procedure is said to be rather painful, but extraordinarily efficacious.

**Lactophenine in the Treatment of Influenza.**—Garzia (*Gazzetta degli ospedali e delle cliniche*, 1895, No. 76; *Centralblatt für innere Medizin*, November 7, 1896) gives from seven to fifteen grains of lactophenine three or four times a day in influenza and its complications. He says it moderates both the fever and the nervous phenomena and shortens the course of the disease. He regards it as far more efficacious than quinine and salicylic acid.

**The Cleveland Medical Gazette.**—It is announced in the November number of the *Gazette* that it has passed into the hands of a corporation, to be known as the Medical Gazette Publishing Company, which has a capital stock of \$10,000. Dr. Samuel W. Kelley will still continue editor of the *Gazette*, with Dr. Frederick K. Smith as business manager. The future prosperity of the *Gazette*, judging from its past history, seems to be assured.

THE  
NEW YORK MEDICAL JOURNAL.  
*A Weekly Review of Medicine.*

Published by  
D. APPLETON & Co.

Edited by  
FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, DECEMBER 5, 1896.

MEDICAL MEN AS CONTRIBUTORS TO GENERAL  
LITERATURE.

WE have often expressed the wish that members of the medical profession would not so generally confine their writing to matters pertaining to medicine, and we have of late been gratified to see signs of a change in this respect. In particular, two publications have recently appeared that are worthy of special mention. One of them is by Dr. Lydston, of Chicago, the advance sheets of which we briefly alluded to several weeks ago.\* The book is an octavo of over six hundred pages, freely and very handsomely illustrated with half-tone and other pictures. The contents are for the most part prose sketches, but here and there there are a few verses also. Dr. Lydston's delineations in words show, it seems to us, that he is possessed of great descriptive powers. We have not space to mention all the notable articles in the volume, but will simply say that we have been most interested in *The Passing of Major Merriwether*. The major's last letter, read after his death, seems specially clever.

As we said in our notice of the advance sheets, we think Dr. Lydston has succeeded with the illustrative designs even better than with the text. Noteworthy among them is one entitled "*When Pharisee meets Pharisee, then comes—Death,*" facing the page on which the article entitled *Several Kinds of Doctors* begins. The tone of Dr. Lydston's book is wholesome where there must have been some temptation to indulge in mysticism, and for that as well as for his cleverness he is to be commended. We hope to see more work of the sort from him—perhaps a continuous story.

The other book to which we would call attention is a dainty little volume of verses by Dr. Gould, of Philadelphia.† The sentiments expressed—and the verses are for the most part sentimental—are most creditable to the author. Of the various poems, those that have pleased us most are *The Ocean* and *Inter Arma Leges Silent*. There is an abundance of humor as well as

sentiment in Dr. Gould's verses, and we have found nothing morbid in them. If some harshness of versification is occasionally met with, it does not destroy or seriously impair the beauty of Dr. Gould's writing. He, too, we hope, will make us better acquainted with his Muse.

THE SERUM TREATMENT OF SYPHILIS AND  
CARCINOMA.

THE *Deutsche Medizinische-Zeitung* for November 12th contains abstracts of two articles one of which, by Professor Tarnowsky, of St. Petersburg, deals with the serum treatment of syphilis alone. It appeared in the *Archiv für Dermatologie und Syphilis*. Reflecting upon the absence of positive results from employing the normal serum of animals, that of animals inoculated with syphilitic products, or that of persons affected with constitutional syphilis, Tarnowsky thought it most rational to use serum obtained by a process as nearly as possible the same as the one employed in the preparation of antidiphtheritic serum, but the practical difficulty presented itself of finding an animal susceptible to syphilis. However, he thinks he has found such an animal in the foal. Although, on inoculation, the foal does not show any outward signs of syphilis, changes extraordinarily like those due to that disease are found in different internal organs and in the blood-vessels and the lymphatic glands in the course of two or three months. Accordingly, he has endeavored to syphilize two foals with moist syphilitic papules by implanting them in incisions into the skin, by applying them to a blistered surface, and by injecting an emulsion of them subcutaneously.

After these inoculations had been many times repeated, blood was drawn from the animals and the serum was administered subcutaneously to six patients, usually in doses of from ten to twenty cubic centimetres. In five of the patients the disease was quite recent and had not been treated before; the remaining one had tertiary manifestations. The therapeutic result was *nil*, even after long persistence in the treatment; the cases followed their course precisely as if no treatment had been practised. Moreover, the injections seemed to have a detrimental effect. Three of the patients lost flesh, their general health grew worse, and they had transitory albuminuria. In four cases an itching erythema appeared, with pains in the muscles and joints, also purpura in two instances. When large doses were used the temperature was decidedly raised.

The other article, by Dr. Ludwik Rekowski, appeared in the *Gazeta lekarska*. It relates to the serum treatment of both syphilis and carcinoma. This author

\* *Over the Hookah. The Tales of a Talkative Doctor.* By G. Frank Lydston, M.D. Illustrated from the Author's Designs by Mr. C. Everett Johnson. Chicago: The Fred. Klein Company, 1896.

† *An Autumn Singer.* By George M. Gould, A.M., M.D. Philadelphia: The J. B. Lippincott Company, 1897.

conceived the ingenious idea of subjecting the serum-yielding animal to a course of injections of antisyphilitic or anticarcinomatous drugs as the case might be—mercury salicylate to generate an antisyphilitic serum and sodium arsenite to render the serum effective against cancer. In the antisyphilitic serum thus produced traces of mercury could be detected by means of chemical tests. It was injected into patients with tertiary syphilis in doses of ten cubic centimetres every third day, and the results are represented as astonishing; as soon as after the third or fourth injection the gummatous lesions began to disappear and soon vanished completely.

Traces of arsenic were found in the anticarcinomatous serum. It was used on two patients with cancer of the face, ten cubic centimetres being injected subcutaneously twice a week for six weeks, and at the end of that time the author was satisfied that the patients' general condition had improved notably. What the ultimate results were is not stated. On the whole, it can hardly be said that these two communications are very encouraging; they both show, however, that no stone is to be left unturned to perfect the serum treatment of disease and to extend the field of its application.

#### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 1, 1896 :

DISEASES.	Week ending Nov. 24.		Week ending Dec. 1.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	34	6	28	9
Scarlet fever.....	135	8	113	9
Cerebro-spinal meningitis....	2	2	3	2
Measles.....	81	3	89	2
Diphtheria.....	218	18	261	30
Tuberculosis.....	188	98	122	81

**St. Christopher's Hospital for Babies.**—On December 1st there was opened at No. 283 Hicks Street, near Joralemon, Brooklyn, Saint Christopher's, a hospital for babies. It is expected that this hospital will be to Brooklyn what the Babies' Hospital is to New York. The announcement mentions the difficulty of getting hospital treatment for the very young, and says that this hospital proposes to accept just such patients. No child suffering with a contagious disease can be received, but all others, sick and destitute, will be taken to the full capacity of the hospital. The following-named gentlemen constitute the hospital staff: Consulting surgeons, Dr. A. J. C. Skene and Dr. William Maddren; consulting physician, Dr. Charles Jewett; consulting neurologist, Dr. William Browning; consulting laryngologist, Dr. William F. Dudley; consulting ophthalmologist, Dr. William H. Snyder; visiting pediatricists, Dr. William A. Northridge and Dr. John W. Parrish.

**The Semicentennial Meeting of the American Medical Association.**—The meeting is to be held in Philadelphia, on June 1, 2, 3, and 4, 1897. In view of the fact that it will occur in a great medical centre and near the other great

cities of the eastern coast, the committee of arrangements has already made provision for the accommodation and entertainment of the delegates, by the engagement of the Academy of Music, Horticultural Hall, the South Broad Street Theatre, and the large meeting rooms in the Hotel Walton and Hotel Stenton. As these large buildings are all within a short distance of the great railroad stations in the centre of the city, and are all situated within one block on both sides of Broad Street, every department of the meeting will be conveniently arranged. At the last meeting of the association it was voted to devote the first evening of the meeting, that of Tuesday, June 1st, to dinners of the various sections. The officers of the sections desiring to give such a dinner are asked to communicate with Dr. G. E. de Schweinitz, chairman of the subcommittee on accommodation, No. 1401 Locust Street, Philadelphia, as early as possible, in order that dining rooms may be engaged or other entertainment provided. As it is expected that fully three thousand physicians will be present, the committee suggests that application for accommodations be made as early as possible. It is hoped that every member of the association will make a special effort to attend. Further circulars of information will be issued by the committee from time to time. Individuals and firms desiring space for exhibition in the Exhibition Hall, which will be in the same block as the various meeting halls, will please apply promptly to the chairman of the subcommittee on exhibits, Dr. Edward Jackson, No. 1633 Locust Street, Philadelphia.

**The New York Academy of Medicine.**—At the regular meeting of Thursday evening, the 19th ult., an anniversary discourse entitled *The Evolution of the Surgery of the Twentieth Century* was delivered by Dr. George R. Fowler.

At the last regular meeting, on Thursday, the 3d inst., a paper on *The Management of Pneumonia* Patients was to be read by Dr. S. Baruch, and discussed by Dr. Charles B. Folsom, of Boston; and Dr. W. H. Draper, Dr. A. A. Smith, Dr. E. G. Janeway, Dr. W. P. Northrup, and Dr. Alfred Meyer.

At the last meeting of the Section in Orthopædic Surgery, on Friday evening, the 20th ult., a paper entitled *The Treatment of Lateral Curvature by Light Gymnastic Movements* was read by Dr. James K. Young, of Philadelphia, and discussed, as stated in last week's issue.

At a special meeting of the Section in Obstetrics, on Friday evening, the 27th ult., Dr. J. Clifton Edgar read a paper on *The Treatment of Eclampsia*, which was discussed by Dr. Davis and Dr. Hirsch, of Philadelphia; Dr. Reynolds and Dr. Green, of Boston; Dr. Jewett, of Brooklyn; and Dr. Grandin and Dr. Lusk, of New York.

At the next meeting of the Section in Genito-urinary Surgery, on Tuesday evening, the 8th inst., Dr. William K. Otis will read a paper entitled *The Detection of Stone in the Bladder*, and Dr. Robert C. Kemp will exhibit a double-current rectal irrigator and a prostatic cooler. Cases will also be presented.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 10th inst., the following papers will be read: *Fatty Liver and Ileocolitis*, by Dr. R. G. Freeman; and *The Treatment of Diphtheria; an Inquiry into Modern Methods employed in Berlin in the Summer of 1896*, through the Courtesy of Professor Baginsky, by Dr. Louis Fischer. Dr. J. S. Ferguson will present an infant with pseudo-leucæmia.

**The Late Dr. Frank Whitman Ring.**—The following resolutions were adopted by the medical board of the Manhattan Eye and Ear Hospital on July 17, 1896:

*Whereas*, The hand of Death has removed from our midst our executive surgeon, Dr. Frank W. Ring,

*Resolved*, That in submitting to the will of Almighty God, we wish to express our personal sorrow at the loss of a most faithful and efficient colleague.

*Resolved*, That we extend to his widow and family our deepest sympathy in their bereavement.

*Resolved*, That the surgical staff of the hospital attend his funeral services in a body, and that a committee of four be appointed to accompany his remains to their final resting place.

*Resolved*, That the flag of the hospital be displayed at half-mast until after his interment.

*Resolved*, That a copy of these resolutions be forwarded to his widow.

The following resolutions were adopted by the board of directors, at their stated meeting, on November 17, 1896:

*Whereas*, We are called upon to record the death of our associate, Dr. Frank Whitman Ring, which occurred on July 17, 1896, and whereas Dr. Ring has, for the past twelve years, been actively connected with the Manhattan Eye and Ear Hospital, New York.

*Resolved*, That we heartily indorse the action taken by the medical board at the time of his death.

*Resolved*, That we hereby express our love and appreciation of Dr. Ring as a man, a surgeon, and a director of this hospital, and our own sorrow as well as the loss to the institution by his untimely death.

*Resolved*, That a copy of these resolutions, in conjunction with those passed by the medical board, be published in our *Annual Report*, the New York medical journals, and the *Maine Journal of Medicine and Science*, and that a copy of these resolutions be sent to his widow with the sympathy of this board.

DAVID WEBSTER, M. D.,  
[Signed.] J. B. EMERSON, M. D., } Committee.  
JOHN STEWART.

**The Buffalo Academy of Medicine.**—At the last meeting of the Section in Surgery, on Tuesday, December 1st, the order for the evening was as follows: A paper entitled *A Brief Review of the General Technics of Certain Cranio-cerebral Operations*, by C. B. Nancrede; and the presentation of cases by Dr. Roswell Park, Dr. E. A. Smith, Dr. W. C. Phelps, and Dr. E. J. Meyer.

**The New York Otological Society.**—Officers have lately been elected as follows: President, Dr. Gorham Bacon; vice-president, Dr. C. J. Kipp; secretary and treasurer, Dr. H. A. Alderton; members of the committee on admissions, Dr. Edward B. Dench, Dr. M. Toeplitz, and Dr. N. J. Hepburn.

**A Clinic for Defective Speech.**—The Polyclinic Hospital in Philadelphia has established a department for the cure of speech defects which do not require surgical or special medicinal treatment. The department will take patients that need training in vocalization and articulation.

**The Health of Dr. Howard A. Kelly, of Baltimore.**—We are happy to be able to state that Dr. Kelly has entirely recovered from the illness which compelled him to relinquish his practice for a time, and that he is now actively engaged in his professional work.

**The New York Hospital.**—Dr. Samuel W. Lambert has been appointed an attending physician to the hospital.

**Changes of Address.**—Dr. E. H. Cook, from New York to No. 179 Amity Street, Flushing, N. Y.; Dr. William G. Schaffner, from Beirut, Syria, to Lakewood, N. J.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 15 to November 21, 1896:*

BROOKE, BENJAMIN, First Lieutenant and Assistant Surgeon, is ordered to Chicago to appear before the Examining Board for examination as to his fitness for promotion.

HALL, JOHN D., Major and Surgeon, is relieved from duty at Madison Barracks, New York, and ordered to Fort Wadsworth, New York, for duty, relieving COMEGYS, EDWARD T., Major and Surgeon. Major COMEGYS, on being thus relieved, is ordered to Fort Sill, Oklahoma Territory, for duty.

LAUDERDALE, JOHN V., Major and Surgeon, is retired from active service. November 13, 1896.

CLOUD, MARSHALL MORGAN, First Lieutenant and Assistant Surgeon, will report in person to the president of the Army Medical School, Washington, D. C., for the course of instruction.

SMITH, LOUIS PERCY, First Lieutenant and Assistant Surgeon, will report in person to the president of the Army Medical School, Washington, D. C., for the course of instruction.

SWIFT, EUGENE L., Captain and Assistant Surgeon. The leave of absence granted him on surgeon's certificate of disability is extended two months on account of sickness.

TESSON, LOUIS S., Major and Surgeon, is granted leave of absence for four months, to take effect about December 5, 1896.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending November 23, 1896:*

BRODERICK, R. G., Assistant Surgeon. Ordered to the U. S. Steamer Constellation.

CABELL, A. G., Surgeon. Detached from the U. S. Steamer Michigan, ordered home, and granted three months' leave of absence.

CORDEIRO, F. J. B., Passed Assistant Surgeon. Detached from the U. S. Steamer Constellation and ordered to the U. S. Steamer Michigan.

DIXON, W. S., Surgeon. Detached from special duty in Washington and ordered to the U. S. Steamer Brooklyn.

MORRIS, L., Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, ordered to examination for promotion, at New York, and placed on waiting orders.

WALTON, T. C., Medical Director. Detached from the Naval Academy on January 18, 1897, instead of on December 15, 1896, and ordered to the Naval Laboratory, New York, January 19, 1897.

WELLS, H. M., Medical Director. Detached from the Naval Laboratory, New York, on January 19, 1897, instead of on December 19, 1896.

**Marine-Hospital Service.**—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Fifteen Days ending November 15, 1896:*

BROOKS, S. D., Passed Assistant Surgeon. Directed to assume temporary command of Port Townsend, Washington, Quarantine during the absence of Passed Assistant Surgeon W. G. Stimpson. November 10, 1896.

MCINTOSH, W. F., Passed Assistant Surgeon. Granted leave of absence for five days. November 5, 1896.

YOUNG, G. B., Passed Assistant Surgeon. Leave of absence extended two days. November 9, 1896.

STIMPSON, W. G., Passed Assistant Surgeon. To proceed from Port Townsend, Washington, to Angel Island, California, Quarantine for temporary duty. November 10, 1896.

NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for four days. November 9, 1896.

STEWART, W. J. S., Passed Assistant Surgeon. Granted leave of absence for three days. November 7, 1896.

#### Board Convened.

Board convened to meet in Washington, D. C., for the physical examination of an officer of the Revenue-Cutter Service. Surgeon FAIRFAX IRWIN, chairman; Surgeon C. E. Banks, and Passed Assistant Surgeon B. W. Brown, recorder.

#### Promotion.

CARMICHAEL, D. A., Passed Assistant Surgeon. Commissioned as Surgeon. November 14, 1896.

#### Society Meetings for the Coming Week:

MONDAY, December 7th: New York Academy of Sciences (Section in Biology); New York Medico-surgical Society; German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pitts-

burgh, Pennsylvania, Medical Society; Chicago Medical Society; Cleveland Medical Library Association (annual).

**TUESDAY, December 8th:** New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Medical Societies of the Counties of Oswego (semiannual—Oswego), Rensselaer, and Ulster (quarterly), N. Y.; Newark (private) and Trenton, N. J., Medical Associations; Morris, N. J., County Medical Society (semiannual); Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

**WEDNESDAY, December 9th:** Society of Alumni of the City (Charity) Hospital, New York; New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Medical Societies of the Counties of Albany and Montgomery (annual), N. Y.; Pittsfield, Massachusetts, Medical Association (private); Philadelphia County Medical Society.

**THURSDAY, December 10th:** Society of Medical Jurisprudence and State Medicine, New York; New York Laryngological Society (annual); Brooklyn Pathological Society; Medical Society of the County of Cayuga (semiannual), N. Y.; South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

**FRIDAY, December 11th:** Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.; St. Louis Academy of Medical and Surgical Sciences; Cleveland Medical Society.

**SATURDAY, December 12th:** St. Louis Medical Society; Obstetrical Society of Boston (private).

## Births, Marriages, and Deaths.

### Married.

**HILL—BRUNSON.**—In Edgefield, South Carolina, on Tuesday, November 24th, Dr. John W. Hill and Miss Susie Brunson.

**LEONARD—BIXBY.**—In Buffalo, on Tuesday, November 24th, Dr. Allen Thomas Leonard, of North Tonawanda, N. Y., and Miss Inez Mason Bixby.

**OLCOTT—LOUGHRAN.**—In Brooklyn, on Saturday, November 28th, Dr. Charles A. Olcott and Mrs. Susan B. Loughran.

**SIMS—CALDWELL.**—In Maybinton, South Carolina, on Wednesday, November 25th, Dr. W. L. Sims and Miss Mattie Caldwell.

**THIGPEN—BISSELL.**—In Charleston, South Carolina, on Tuesday, November 17th, Dr. Charles Alston Thigpen, of Montgomery, Alabama, and Miss Daisie Lee Bissell.

### Died.

**BILLIU.**—In Shreveport, Louisiana, on Wednesday, November 25th, Dr. Morgan Billiu, son of Dr. David H. Billiu, in the twenty-eighth year of his age.

**CUTTER.**—In New York, on Tuesday, November 24th, Ellen Bigelow, wife of Dr. John Ashburton Cutter.

**ELIOT.**—In New Haven, on Monday, November 30th, Mary A. Forbes, wife of Dr. Gustavus Eliot.

**ELLSWORTH.**—In Hartford, Connecticut, on Sunday, November 29th, Dr. Pincney Webster Ellsworth, aged fifty-three years.

**FIELD.**—In Bayonne, New Jersey, on Wednesday, November 25th, Dr. Jacob T. Field.

**HARRISON.**—In Keokuk, Missouri, on Tuesday, November 24th, Dr. V. H. Harrison, aged sixty years.

**HOLLEMBÆK.**—In Burlington, Vermont, on Thursday, November 5th, Dr. Henry H. Hollembæk.

**LEAKE.**—In New Orleans, on Saturday, November 28th, Dr. James Leake, in the thirty-fifth year of his age.

**McCLURG.**—In West Chester, Pennsylvania, on Tuesday, November 3d, Dr. John Russell McClurg.

**NIMOCKS.**—In Lawrence, Mississippi, on Friday, November 27th, Dr. T. B. Nimocks.

**WILLIAMS.**—In Baltimore, on Saturday, November 21st, Dr. Philip C. Williams, aged sixty-eight years.

**WISE.**—In Trenton, South Carolina, on Wednesday, November 25th, Mrs. G. W. Wise, wife of Dr. G. W. Wise.

## Letters to the Editor.

### THE INCOMPATIBILITY OF ANTIPYRINE AND CALOMEL.

112 EAST 128TH STREET, NEW YORK, November 21, 1896.

To the Editor of the *New York Medical Journal*:

SIR: It is unpleasant to appear in the rôle of a critic; we are all fallible, we are all liable to err. But when a writer of an article, starting from false premises, arrives at wrong conclusions, and those conclusions, if accepted as the truth and applied in practice, might lead to unpleasant consequences, then it becomes the duty—unpleasant as it may be—of those who are in a position to do so to correct such statements and point out where the error lies.

Dr. Rosenau, in this week's issue of the *Medical Journal*, says he does not believe in the incompatibility of antipyrine and calomel, because he has seen no untoward effects from their simultaneous administration. Well, that those two drugs are incompatible has been known for nearly a decade, and they are stated to be so in all the authoritative reference books. That knowledge must certainly have been gained through facts and investigations. But we will let that—the question of authorities—pass. Dr. Rosenau states his opinion that the assertion that a large amount of mercuric chloride is generated is probably based on laboratory experiment, and that in the economy neither drug recognizes the presence of the other. Now, in the first instance, it will not do to sneer at laboratory experiments; too much is the science of medicine indebted to that of chemistry. It is true that test-tube experiments do not *always* accord with results obtained in the animal economy, but they oftener do than not. In the second instance—and this is an important point for the doctor to remember—we do not at all maintain that the mercurous is converted into mercuric chloride in the economy. It is *before it enters the economy*, it is in the pharmacist's laboratory, while being rubbed in the mortar, while lying in intimate contact in the "char" or capsule, that the chemical interaction takes place. I have no objection to giving those drugs separately, even only five minutes apart; there is no fear of their reacting upon one another in the stomach or alimentary canal, as they will not be "intimate" enough to do it. The same holds true of antipyrine and nitrous ether. I frequently prescribe a dose of antipyrine to be followed in a few minutes by a large dose of the spirit of nitrous ether (in order to counteract the cardiodepressant effects of the former, and to act synergistically with it, as a febrifuge); but I would most emphatically protest against prescribing those two drugs in the same bottle. The new nitrous compound—of a beautiful grass-green color—which forms in the bottle

within a few minutes is a most treacherous and dangerous substance. And now as to Dr. Rosenau's statement that he has never seen any bad effects from the administration of antipyrine and calomel simultaneously. This I am only too willing to believe. The doctor has been prescribing from a twelfth to a quarter of a grain of calomel *pro dosi*. As it is not maintained that the whole amount of calomel becomes converted into bichloride, but only a small proportion, say one eighth, the amount of bichloride formed in each powder would be from one ninety-sixth to one thirty-second of a grain, and such a quantity could not produce any injurious effects, even in a young infant. But antipyrine and calomel are prescribed in doses of from ten to thirty grains and from five to ten (or even fifteen) grains, respectively. And when a powder is prescribed containing ten grains of each of the drugs an amount of bichloride may be generated which may produce, not fatal, but toxic effects. It may not happen in every case, but as it has happened in some cases—one within my personal knowledge—we do not want to forget that fact. And another important point: Antipyrine, though a fairly stable compound, is nevertheless so easily affected by a great number of substances that the safest way is to prescribe it alone or only with drugs which we know have no injurious effect upon it.

WILLIAM J. ROBINSON, M. D., Ph. G.

## Proceedings of Societies.

### NEW YORK STATE MEDICAL ASSOCIATION.

*Thirteenth Annual Meeting, held in New York, on Tuesday, Wednesday, and Thursday, October 13, 14, and 15, 1896.*

The President, Dr. DARWIN COLVIN, of Wayne County, in the Chair.

(Continued from page 593.)

#### The Technics of Intubation in Children; Some Remarks on the Time for Operation and After-treatment.—

Dr. THOMAS J. HILLIS, of New York County, read a paper with this title. He recommended that the child should be prepared for intubation by wrapping it in strong muslin, the arms hanging by the sides, and the forearms and hands crossed on the abdomen. This position, and the use of muslin instead of a blanket, secured to the operator more room for the necessary manipulations. Instead of keeping the tube and introducer vertical and in the median line during the whole process of intubation, as was usually done, space could be economized, and in some instances the operation facilitated, by tilting the introducer and tube during the first part of the introduction, so that the tube would lie transversely across the tongue. Of course, as soon as the tube touched the guiding finger, the instrument should be quickly restored to the vertical position in the median line of the body, and inserted into the larynx. Among the various methods that had been proposed for extraction of the tube there was one simple procedure which was applicable to infants under a year old, in whom the cartilaginous rings of the trachea were soft and yielding. This consisted in placing the infant on its back, with a small pillow under the neck, and the head thrown well back, and, by means of the thumb and fingers "expressing" or forcing the tube upward and back-

ward into the mouth, where it could be seized with the thumb and index finger of the disengaged hand. The speaker highly commended the ingenious contrivance for extraction which was invented by Dr. Dillon Brown. He said that no hard-and-fast rule could be laid down as to the number of days the tube should be allowed to remain in the larynx, but it was always well to err on the side of leaving it in a little longer than was absolutely demanded. There would be slight obstruction present for a short time after the removal of the tube, but if this was not very great, it need cause the physician no special uneasiness. It was well known that considerable difficulty was often experienced in feeding children while the tube was in the larynx. The difficulty was commonly overcome by placing the child on the nurse's lap, on its back, with the head hanging down over the edge of the lap. Personally, he preferred to have the little one lie on the stomach, face down, as this gave greater command over the constrictors.

**Temperature as an Element in Prognosis.**—Dr. JOHN SHRADY, of New York County, spoke of the accuracy of the temperature record, as compared with that of the pulse and respirations. It therefore furnished the physician with more reliable information than the other vital signs did, but the temperature record, as an index of the problems of waste and supply, should be ever considered in the light of sex, age, temperament, and environment. A high temperature was not necessarily a signal of danger—a temperature of 106° F. on the second or third day of catarrhal pneumonia was not so grave as a temperature of 105° F. in the second or third week of typhoid fever. Da Costa had reported a recovery in a case of cerebral rheumatism after a maximum axillary temperature of 110° F. A temperature of 96.5° F., he said, was the rule in shock, apoplexy, diabetes, tuberculous peritonitis, cholera, and pulmonary embolism. In the prognosis of all these conditions there were no embarrassments, for the *finale* was not long delayed, and was sure to be gloomy—the fires were low and smoldering. His conclusions were: 1. That high temperatures were not so uniformly fatal in their tendencies as low temperatures. 2. That a high temperature of short duration was simply indicative of an acute infection or of some insignificant disturbance. 3. That a subnormal temperature, as a rule, presaged death. The greatest disappointments were the rule in cases of collapse.

**The Medical Treatment of Inebriety.**—Dr. T. D. CROTHERS, of Hartford, Connecticut, read a paper on this subject in which he entered a plea for a more careful and general study of inebriety by physicians, particularly as regarded the ætiological factors entering into individual cases. He said that the removal of all spirits at the commencement of the treatment was always followed by the best results, and the reaction could be effectually neutralized by giving a twentieth of a grain of nitrate of strychnine, every four hours, with the bromides for the relief of insomnia. This treatment should be supplemented by a calomel purge, the use of hot baths, and vigorous massage, and by the administration at stated intervals of such nourishment as hot broths. Where a gradual withdrawal of spirits was insisted upon, the form of spirits should be changed to the wines and beers. It would be found that the withdrawal of liquor in these cases often resulted in the sudden and unexpected development of grave organic disease—*e. g.*, tuberculosis and dementia. Inebriety was not infrequently the result of an unusual and pro-

longed strain, or was due to climatic conditions and environment; hence, when such factors were present, every effort must be made to eliminate these factors, otherwise there would be a speedy relapse. Some of the preparations were useful in averting the "drink storm," but the administration of drugs, like apomorphine, with the idea of causing a disgust for liquor, was always dangerous and rarely satisfactory. The keynote to the successful treatment of these cases was to be found in sharp elimination. Where the bromides were indicated, they should be given in large doses—from fifty to a hundred grains—but these doses should not be continued for more than a very few days. No single remedy was capable of meeting a wider range of conditions than the Turkish bath associated with massage.

**The Surgical Relief of Obstruction of the Common Duct by Biliary Calculi.**—Dr. H. O. MARCY, of Boston, described in this paper the operation which he had been the first to do for the removal of calculus situated in the common duct. The original operation had been done on October 20, 1889, according to the following method: The walls of the common duct were divided with scissors and their edges everted from over the calculus, the abdominal cavity having been previously shut off from the field of operation by sponges. With a fully curved needle armed with selected tendon suture, the divided edges of the thickened mucous membrane of the duct and gall bladder were united by a continuous suture. Over this the peritoneal edges were coaptated by a layer of continuous suture, and then a third layer of tendon sutures was applied, the sutures being taken parallel to the long axis of the wound, and through the peritonæum. Tension on this suture buried not it alone, but also the uninjured peritonæum. After the removal of the sponges, the peritonæum was closed with a continuous double tendon suture. The divided muscular structures were united in a similar manner in separate layers, and the skin was coaptated by a layer of buried tendon sutures. The wound was sealed with collodion. Convalescence was rapid. The calculus, when dried, weighed fifty-nine grains.

**A New Microtome.**—Dr. SIDNEY YANKAUER, of New York County, exhibited a simple and very inexpensive microtome which he had devised, which had been proved capable of doing as good work as the more expensive instruments. With the rude model shown, he said, he had cut sections in celloidin a thousandth of an inch thick, and in paraffin sections only one five-thousandth of an inch thick.

**A Successful Plaster-of-Paris Bandage Cutter.**—Dr. YANKAUER also exhibited a new instrument for cutting plaster of Paris. It consisted of a series of peculiarly ground knife blades arranged around the periphery of three wheels, which were all fastened to one axle and were rotated after the manner of a circular saw. This peculiar construction permitted of a very rapid and easy cutting action, and kept the teeth free from clogging.

**Physiological Deductions regarding the Usefulness of So-called Animal Extracts.**—Dr. H. A. HAUBOLD, of New York County, took the position that these substances must be so altered by digestion and other changes that there was no reason to suppose that they reached the tissues in a form which would exert any specific action. It had been alleged that when the nucleins were administered hypodermically they gave rise to a leucocytosis, but, while this was a fact, it only seemed to show that the blood made a special effort to rid itself of this foreign body.

**A Point in the Treatment of Endometritis.**—Dr. WILLIAM H. ROBB, of Montgomery County, advocated a more general use of nitrate of silver in the treatment of endometritis. His plan was to make no intra-uterine applications without rigid antiseptic precautions, and if the drainage was not sufficient, to attend to this matter at once. Incidentally, of course, injuries were repaired and displacements reduced. The application of the nitrate of silver should be made carefully and thoroughly, and to do this it was absolutely necessary that all unhealthy secretions should be removed previously from the interior of the uterus, and the latter be left clean and dry. For mild cases and those seen early he preferred to use a five- or ten-grain solution of nitrate of silver, but the more chronic cases required very much stronger solutions or even a light touching with the solid stick.

Dr. L. J. BROOKS, of Chenango County, said that he would not deny that such applications were followed immediately by an apparent improvement or cure, but further observation would show that a real cure had not been effected, but that, on the contrary, the treatment had left an atrophic, non-secreting, and irritable endometrium. There was no such objection to the use of the curette.

Dr. J. FRANCIS CALEF, of Middletown, Connecticut, said that he had found a weak solution of nitrate of silver, 1 to 3,000, soothing to an inflamed mucous membrane, but to use these very dilute solutions effectively the water for washing the surface must be free from chlorides.

Dr. JOHN CRONYN, of Erie County, said that he had frequently seen much benefit from the application of strong solutions of nitrate of silver to the endometrium.

**A Class of Fatal Cases Presumably Due to Intestinal Ptomaines.**—Dr. E. D. FERGUSON, of Rensselaer County, described the histories of eight cases—four medical and four surgical—in which the chief feature had been the sudden onset of symptoms, vomiting, at first, of watery mucus containing a few dark specks, and later the vomiting of coffee-ground material, and the development of a slight icterus. Death had occurred in about forty-eight hours. The cases had not been in the same locality, and had occurred at different times, extending over a period of a number of years. In the autopsies that had been obtained there had been no evidence of intestinal obstruction, peritonitis, or sepsis, but the liver had been the seat of parenchymatous inflammation, with softening and acute atrophy. Intestinal obstruction could certainly have been excluded in some of the cases, as, for instance, in one in which there had been free movements of the bowels up to the day of death. The only explanation that he could offer was that the condition had been an acute toxæmia resulting from the accumulation of a bacterial ferment or an enzyme in the blood, or else that through some extraordinary influence of the nervous system the digestive and assimilative processes had been so interfered with that a virulent form of poisoning had been produced.

**Two Interesting Cases of Surgery of the Kidney.**—Dr. J. E. JANVRIN, of New York County, reported a case of multiple abscess of the kidney, with nephrectomy and death from uræmia, and a case of fibrolipoma of the kidney capsule, with successful laparotomy.

**The Palliative Treatment of Cancer of the Cervix Uteri and Bladder.**—Dr. NATHAN G. BOZEMAN, of New York County, advised that the strictured condition of

the vagina should be remedied by the wearing, for a few hours daily, of intravaginal dilators, and that where the disease had produced a vesico-vaginal fistula irrigation should be performed. This last was best accomplished by the patient wearing the Bozeman vesical drainage support, and using it in conjunction with his intermittent siphon apparatus, by which continuous irrigation could be kept up for three hours at a time.

**The Bromides as a Cure in Diphtheria.**—Dr. ROBERT ABERDEIN, of Onondaga County, presented a paper on this subject in which he stated that he had been led to adopt the treatment by an accidental observation regarding the action of the bromides in an epidemic of diphtheria that had occurred in an asylum. His experience with this treatment had comprised thirty-eight cases, with only two deaths. He expressed the greatest confidence in its value.

**Recent Investigations concerning Eclampsia.**—Dr. W. T. LUSK, of New York County, opened the discussion of this subject by calling attention to the fact that many pregnant women had albuminuria without eclampsia, and that many others had eclampsia without any evidence of abnormality in the urine. It was now well known, he said, that many poisons resulting from excessive tissue change might give rise to convulsions, and it was well to remember that a diminution in the quantity of urea indicated an excess of the other poisons resulting from tissue metabolism. It was not improbable that eclampsia might result from intestinal decomposition and the formation of certain toxins. A plan of treatment now finding much favor in Europe consisted in keeping pregnant women who exhibited slight albuminuria, with perhaps slight nervous symptoms, on a rigid milk diet and carefully regulating the bowels. Personally, he would not care to interfere with pregnancy where the only symptom of disorder was a slight albuminuria. Where interference was demanded, he preferred to induce labor by the use of Barnes's bags, except in the rare and extremely urgent cases where it seemed justifiable to still further expedite labor by making Dührssen's incisions into the cervix. When it became necessary to resort to these incisions, they should be closed again by suture immediately after delivery. Where a patient with puerperal eclampsia had turgid blood-vessels no known remedy could equal the removal of sixteen ounces of blood from the arm. Veratrum viride was at present attracting attention in Europe, but he had had no personal experience with it in the treatment of puerperal eclampsia.

Dr. E. R. SQUIBB, of Kings County, recommended the employment of the official fluid extract of veratrum viride, in doses of five minims every ten or fifteen minutes, until the pulse had been affected by it; after this, the drug should be administered for some time longer, but in diminished doses. Norwood's tincture was of very variable strength. The pulse was sometimes apparently feeble, but even here the veratrum should not be withheld, but given in smaller doses.

The PRESIDENT said that he usually gave not more than five minims of the veratrum, repeating the dose in half an hour. The pulse was certainly sometimes quite deceptive; even when it was apparently feeble it was proper to give veratrum and bleed.

**The Duty of the Public to the Physician.**—Dr. WILLIAM M. BEMUS, of Chautauqua County, presented a paper with this title in which he reviewed some legal points of general interest to the physician. He called attention to the fact that if a physician was sued by

some charity patient, even though the case was decided in his favor, and the plaintiff ordered to pay the costs, the physician would find that he would have to foot his own bill, being the only responsible party. Malpractice could only be affirmed when the physician deliberately set aside well-known principles. As a rule, anything warranted by good practice and not objected to by the patient was justified in law. The prescription had been decided to be the property of the patient, and, while the druggist had a right to retain it as a voucher, he had no legal right to renew or duplicate it without the knowledge and consent of the prescriber.

**A Plea for the General Use of Measures to Prevent Ophthalmia Neonatorum.**—Dr. A. A. HUBBELL, of Erie County, read a paper on this subject in which he showed that one or two children out of every thousand born in this country had ophthalmia neonatorum, and that about fifteen per cent. of those who had had this disease and had not been properly treated became blind in both eyes. He described various methods of prophylaxis, and showed by statistics from different institutions what a remarkable reduction in the percentage of children having ophthalmia neonatorum had been effected by the systematic use of the now well-known Credé method. This consisted in giving the child a bath immediately after ligating the funis, and then, after wiping the eyelids with absorbent cotton, instilling into each eye a drop of a ten-grain solution of nitrate of silver. As ophthalmia neonatorum developed where there had been not the slightest ground for suspecting that the mother had had gonorrhoea, the only effective method of prophylaxis presupposed the employment of the treatment in every newborn child.

**The Address in Surgery** was delivered by Dr. CHARLES PHELPS, of New York County. The first part dealt principally with a consideration of the remarkable impetus that had been given to surgery by advances in the modern science of bacteriology. The remainder of the address was devoted to ethical matters, principally the common practice of exploiting surgical operations in the daily newspapers.

**Supplementary Notes upon Tendon-grafting and Muscle-transplantation for Deformities following Infantile Paralysis.**—Dr. S. E. MILLIKEN, of New York County, presented a paper on this subject which was supplementary to a similar communication presented a year ago. He said that he had operated in this class of cases altogether fourteen times, and in only one instance had there been a failure to get union. He preferred to use kangaroo tendon on the tendons and muscles in the closure of the sheath, and interrupted catgut for the wounds in the skin. The limb should, of course, be perfectly immobilized by means of plaster of Paris. The best results were obtained in young children.

**Auscultatory Percussion.**—Dr. LOUIS L. SEAMAN, of New York County, exhibited his perfected instrument for practising auscultatory percussion without the aid of a second person. He also showed a very superior form of stethoscope which he said had come into vogue in Europe. It consisted of a small hard-rubber chamber, closed at the lower, or chest, end with a diaphragm not unlike that used in the telephone, and at the upper end by a rubber cover through which soft-rubber tubes passed up to the ears. He stated that in this form of stethoscope extraneous sounds caused but little inconvenience, and that auscultation was very satisfactory with it, even though it was applied to an irregular surface. When it was desired to localize the sounds more accu-

rately, this could be accomplished, he had found, by screwing a hard-rubber stem into the diaphragm.

**The Peripheral Neuralgias of Traumatic Origin.**—Dr. THOMAS H. MANLEY, of New York County, expressed the belief that the protoplasm of the blood played a direct and important part in the causation of painful affections of the nerves.

(To be continued.)

## Book Notices.

*Genius and Degeneration.* A Psychological Study.

By Dr. WILLIAM HIRSCH. Translated from the Second Edition of the German Work. New York: D. Appleton & Co., 1896. Pp. vi-333. [Price, \$3.50.]

THE author of this book is well fitted by education and by temperament for the task he has undertaken. His thorough acquaintance with the subject from its varied standpoints of literature, art, and music is evident on every page, while his judicial attitude is commendable.

At the beginning the need appears of precision in the definition of the three words genius, insanity, and degeneration, and the importance is made clear of reaching a common concept on which all may agree before conclusions as to the conditions or types can be drawn. That there are difficulties in the way to that end is shown by the numerous attempts which have been made, all of which are, to the author, more or less deficient from a scientific point of view.

Moreover, the translator's responsibility is great in a subject in which fine psychological shades of meaning are important.

Two types of genius, as represented by Goethe and Schiller, are studied at some length, the former unconventional, spontaneous, subjective; the latter formal and objective, but both have "creative fancy." This leads no nearer an understanding of the word, for if among geniuses are to be included scientific men, generals, statesmen—and who would deny that Newton and Napoleon were men of genius?—the qualifications of genius seem to the author to be entirely different, for "fancy never discovered bacteria . . . nor has it been successful as a method of medical diagnosis." So the conclusion is reached that "genius in different departments is referable to the most diverse psychical conditions," and that no psychological meaning can be attached to the word. It is evident that this result, while possible to a German, loses much of its significance in the English language. We would certainly not deny that a great diagnostician had imagination, although perhaps not *Phantasie*. As Ladd says, "It is a serious mistake to suppose that a student of any science can be great without a strong and lofty imagination."

The author refutes the extreme views of Lombroso and Moreau, and shows the fallacy of their assertions that men of genius are insane because of their "sporadic sense-deceptions" and the similarity which exists between many of the characteristics of minds at either end of the human scale, which similarity is purely external.

The chapter on degeneration shows still more clearly the inexactness of the quasi-scientific writings on that subject and the confusion that has arisen from them, a confusion which the author does not wholly escape in

his allusions to "higher degenerates" and "pseudo-geniuses."

It would be interesting to follow the author through the entertaining chapter on the influence of education on genius and those on secular hysteria (*Zeithysterie*) and art and insanity, in which the polemic becomes acute. Taking Wagner as an example, the absurdities of the amateur psychiatrist are well shown. The author is evidently an enthusiastic Wagnerian and a cultivated musician. And, although to-day Wagner needs little defense with the public, the review of his psychological attitude toward the world and his art will be read with interest.

The writings of Nordau have had a certain vogue because of their audacity. After the first surprise, it is doubtful whether thoughtful readers have taken him seriously. Dr. Hirsch has stated the position of all conservative thinkers clearly and with dignity, and has done an important service to art in defending what is good and noble in it from the attacks of cynics and pessimists.

The publishers' work, especially as regards the paper and typography, is remarkably good.

*An American Text-book of Physiology.* By HENRY P. BOWDITCH, M. D., JOHN G. CURTIS, M. D., HENRY H. DONALDSON, Ph. D., W. H. HOWELL, Ph. D., M. D., FREDERIC S. LEE, Ph. D., WARREN P. LOMBARD, M. D., GRAHAM LUSK, Ph. D., W. T. PORTER, M. D., EDWARD T. REICHERT, M. D., and HENRY SWALL, Ph. D., M. D. Edited by WILLIAM H. HOWELL, Ph. D., M. D., Professor of Physiology in the Johns Hopkins University, Baltimore, Md. Fully illustrated. Philadelphia: W. B. Saunders, 1896. Pp. 16-17 to 1052. [Price, \$6.]

It must be said in all fairness that this work is free from the faults which are so much dwelt upon as inherent to variorum works, repetition and inconsistency. Every article in this text-book is a monograph written by a teacher most able to expound the principles involved, and the harmonizing work of the editor is only occasionally seen. A brief review only can be given in these pages, although the importance of the work demands much greater space.

The introduction, by Professor Howell, is a logical exposition of the needs of the student of physiology and of what this study involves. The chapter on the general physiology of muscle and nerve, by Professor Lombard, is an exhaustive *résumé* of the functions of these structures. In the succeeding four chapters, Professor Howell writes on secretion, on the chemistry of digestion and nutrition, on the movements of the alimentary canal, the bladder, and the ureter, and on the blood and lymph. The recent investigations upon the ductless glands are fully recorded, and Heidenhain's theory as to the functions of the glomeruli of the kidney is practically accepted. The succeeding chapters bear the marks of wide reading and of thorough investigation.

The chapter on the mechanics of the circulation of the blood and on the movement of the lymph, by Professor Curtis, bears out that physiologist's favorable reputation. The chapter is very clearly written, the deductions are logically made, and the arrangement of the subheadings adds to the value of the article. The nervous influences acting upon the heart and blood-vessels and the nutrition of the heart are thoroughly treated of by Professor Porter. Respiration and animal heat are

assigned to Professor Reichert and the chapters are written with care and exhaustiveness. The ranges of temperatures found in abnormal conditions, from 76.2° to 122° F., are explained on the ground of nervous disturbance, and the fallacy is made clear that bodily temperature varies directly with heat-production.

When one reads the chapter on the central nervous system, by Professor Donaldson, it may be seen what advances have been made in actual physiological knowledge within recent years. It reads no more like analogous chapters in text-books of ten years ago than they did like those of fifty years since. It is sufficient to state at this time that there is little that is valuable in recent literature that has escaped record here.

The chapters on vision, by Professor Bowditch, and on the other special senses, by Professor Sewall, are succeeded by a chapter which treats of the voice and speech and the action of locomotor mechanisms. They are in keeping with the standard of the book.

A comprehensive study of reproduction, by Dr. Lee, is next in order. It is not too high praise to say that it is one of the best articles comprised in the volume. It is exhaustive and fair, and gives evidence not only of wide reading but of diligent study. We know of no text-book of physiology and of but one similar paper which contains an article on this subject so thorough in its embrace, so impartial in its conclusions, and withal so well written, as this one.

The volume concludes with a very able chapter on the chemistry of the animal body, by Dr. Lusk. The only criticism that might be made of it is that it may be too technical for the student of physiology.

The book is handsomely printed, is profusely illustrated from good cuts, and has a carefully made index. Its value is enhanced by footnote references to the literature of the subject with which each chapter deals. It is safe to predict that the *American Text-book of Physiology* will see several editions.

*Röntgen Rays and Phenomena of the Anode and Cathode. Principles, Applications, and Theories.* By EDWARD P. THOMPSON, M. E., E. E. Concluding Chapter by Professor WILLIAM A. ANTHONY, formerly of Cornell University. Sixty Diagrams. Forty-five Half-tones. New York: D. Van Nostrand & Co., 1896. Pp. xiv-190.

THE timely appearance of this little book will certainly be appreciated by many a scientific reader, for it embodies those matters which bear both directly and indirectly upon the making of Röntgen pictures and presents them as no other book as yet pretends to.

The book is mainly a presentation of the methods and the results of experimentation in anodal and cathodal phenomena, and includes theoretical considerations bearing upon the subjects as well as practical statements of methods and applications. Persons who are destitute of knowledge of electricity will certainly not be in a position to digest and properly assimilate the contents of this volume, and the physician of average information on that subject will encounter much that is beyond him, but he will unquestionably derive from it some portion of information (the brief chapter on the surgical applications of X rays is too scant to satisfy), while to the comprehending student of electrical science the book will unquestionably be a much-appreciated treat, presenting as it does a record of what must be to him an absorbing study.

The illustrations of the book are numerous and admirable and, too, so representative and instructive that even the uninitiated may derive both satisfaction and profit from them.

*Royal Infirmary Cliniques.* By ALEXANDER JAMES, M. D., F. R. C. P. E., Physician to the Royal Infirmary, Edinburgh. Edinburgh: Oliver & Boyd, 1896. Pp. 167. [Price, five shillings.]

Good clinical instruction is an invaluable part of a medical student's education, and the author, recognizing the disadvantages attendant on note-taking, has, for the benefit of his class, published his lectures in various journals. Sixteen lectures are here brought together in book form. The cases chosen for clinical demonstration are, with a few exceptions, those ordinarily met with in hospital practice. The value of the book lies in the clear and comprehensive manner in which the author deals with each subject. A Case of Primary Contracting Kidney is a model representation of what a satisfactory clinical lecture should be. One fact impresses us in all of the clinics, that the cases are well studied before their presentation.

The book is a good one for all students of medicine to read.

*A Pictorial Atlas of Skin Diseases and Syphilitic Affections.* In Photo-lithochromes from Models in the Museum of the Saint-Louis Hospital, Paris. With Explanatory Woodcuts and Text, by ERNEST BESNIER, Physician to the Saint-Louis Hospital; A. FOURNIER, Professor of the Faculty of Medicine; TENNESON, Physician to the Saint-Louis Hospital; HALLOPEAU, Member of the Academy of Medicine, and DU CASTEL, Physician to the Saint-Louis Hospital. With the Co-operation of HENRI FEULARD, Curator of the Museum, and L. JACQUET, Secretary of the Dermatological Society of France, etc. Edited and annotated by J. J. PRINGLE, M. B., F. R. C. P., Assistant Physician to and Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. London: The Rebm Publishing Co., Ltd., and Philadelphia: W. B. Saunders, 1896.

PART IV of the *Pictorial Atlas of Skin Diseases* has been received. Pictorial it is, but artistically below the previous numbers, and anything but up to the standard promised when the atlas first appeared.

The plate illustrating, or rather intending to illustrate, psoriasis is particularly mediocre—the normal flesh tint is dead and the portrayal of the lesions gives but a poor idea of typical silvery scales. The redness spoken of in the text as extending beyond the scales and encircling them with a colored border "*distinctly visible in the plate*" is, to say the least, a chromatic stretch of the imagination, and the description by M. Henri Feulard, who supplies the accompanying text, is based, no doubt, more on his accurate knowledge of the disease than on his familiarity with the plate, or at least his just appreciation of its character. The other plates—three in number, two showing the lesions of mycosis fungoides in an advanced stage and one leprosy of the face—are not bad. The latter disease is generally so characteristic that it would take a pretty poor plate indeed not to give some idea of what it was meant to portray. The text of this number is, as usual, beyond criticism. Professor Besnier shares with Feulard in their excellent articles the credit of whatever benefit

this number affords, but, the feature and value of the *Atlas* being a clinical aid supposed to be due to its illustrations, we hope those to be issued in the future will be what they heretofore have been—the first of their kind—and on a par with the work of the gentlemen who so ably contribute the text.

*The Spas and Mineral Waters of Europe.* With Notes on Balneotherapeutic Management in Various Diseases and Morbid Conditions. By HERMANN WEBER, M. D., F. R. C. P., Consulting Physician to the German Hospital and to the Royal National Hospital for Consumption, Ventnor, etc., and F. PARKES WEBER, M. D., M. R. C. P., Physician to the German Hospital. London: Smith, Elder, & Co., 1896. Pp. xii-380. [Price, \$2.]

ALTHOUGH from force of geographical circumstances this little book may be less interest the American practitioner and therefore may be less widely read in this country, we caution the reader of this review that he should not neglect a book so well written and so valuable, for surely one should know things which happen or exist even beyond the limits of one's locality or neighborhood, and, aside from matters necessarily of local moment, so much of general and important information is presented in this work that much benefit must necessarily follow the reading.

The book opens with a chapter upon the therapeutic use of plain water, and this is immediately followed by one upon the constituents and the classification of mineral waters. To this succeeds a consideration of the actions of mineral waters on the body in their external and internal employments, while Chapter IV deals with the various agents and adjuvants which go to make spa treatment effective, and Chapter V depicts the life at spas and considers the seasons for treatment and its duration as well as "after-cures." Then follow chapters upon the various spas, arranged for consideration upon the basis of chemical or thermal activities. Chapter XVIII concludes the work, and ably treats of the application of balneotherapeutics to morbid states.

The style in which the book is written is notable for its easy, almost conversational tone, and this contributes much to the value of the treatise. Indeed, to read it is heartily to enjoy it, and this is a comment which, as everybody knows, it is seldom possible to make of a medical work. We have derived much pleasure and satisfaction from this book, and we believe that many will do the like.

*Food in Health and Disease.* By I. BURNET YEO, M. D., F. R. C. P., Examiner in Medicine at the Royal College of Physicians, etc. With Illustrations. New and Revised Edition. Philadelphia: Lea Brothers & Co., 1896. Pp. viii-592. [Price, \$2.50.]

WE doubt whether any book upon dietetics has been of greater and more widespread usefulness than this much-quoted and much-consulted work of Professor Yeo's. Every characteristic of the work has contributed to its utility—its comprehensiveness, its well-ordered arrangement, its forcible style, which even the numerous though necessary tabulations and analyses have not sufficed to nullify—moreover, its soundness and accuracy both of judgment and of fact, and finally the compact and therefore the more useful and available form of the volume. These traits have marked the several issues of the work, and the present revised edi-

tion perpetuates them and has naturally the added value of modern corrections and accessions.

Part I, which treats of food in health, is little altered as compared with that part in former editions, but to Part II, on food in disease, there has been a considerable amount of revision and addition. The value of this portion of the work is not to be overestimated. The dietetics of the gouty and of the obese, in particular, is most ably dealt with. The chapter upon special dietetic cures, too, is one from which much valuable information may be derived.

It is not too much to say that this work should have as much of future as it has had of past; indeed, its value is more apparent to-day than ever before.

*Diseases of the Eye.* A Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. DE SCHWEINITZ, A. M., M. D., Professor of Ophthalmology in the Jefferson Medical College, etc. With Two Hundred and Fifty-six Illustrations and Two Chromo-lithographic Plates. Second Edition, thoroughly revised. Philadelphia: W. B. Saunders, 1896. Pp. 7 to 679. [Price, \$4.]

THE fact that this book has passed through two editions and a supplementary edition during the four years of its existence indicates that its merits are appreciated by those for whom it is intended.

It is essentially what it purports to be, a handbook of ophthalmic practice, and whether a text-book serves the best purpose in ignoring the histological standpoint is a question which need not be decided here.

The author shows familiarity with the latest ophthalmological literature, and has, by numerous additions, brought the present edition quite up to date.

There are a few suggestions which it is necessary to make, although the inaccuracies are of minor importance. Not enough stress is laid on the after-treatment, especially the breaking up of adhesions, after Knapp's operation for trachoma. Subconjunctival injections of germicides are certainly of use in progressive ulcer of the cornea, and probably only in this condition. It is inaccurate to say (page 444) that a solid growth is not present if a detachment of the retina is tremulous. It is recognized that a small tumor may cause a large detachment, and that the diagnosis may be impossible at a certain stage. On the twentieth line of page 378 it is probable that the word *by* should be substituted for "to." It adds to the confusion already existing if the retinitis punctata albens of Mooren is called "central punctate retinitis"; if the former disease exists as an entity, it is best to adhere to the form described by Gayet and Dor and by Nettleship, which probably belongs to the large class of congenital degenerative changes of which retinitis pigmentosa is an outspoken example.

It is an ungrateful task to call attention to the faults in a book so uniformly excellent; the merits are so numerous that it is impossible to mention them. The book will recommend itself chiefly by its thoroughly practical tone, its clearness and terseness of language, and its modernism. The publishers' work is excellent.

*Recherches cliniques et thérapeutiques sur l'épilepsie. Phylérie et l'idiotie.* Compte-rendu du service des enfants idiots, épileptiques et arriérés de Bicêtre pendant l'année 1895. Volume XVI.

THIS report of the hospital for epileptic and idiotic children at Bicêtre is a well-illustrated, well-printed,

interesting book. The director of the hospital, M. Bourneville, has gathered some of the more striking cases that were under his care during the year 1895, and offers full descriptions of their clinical courses, of the therapeutic measures pursued, and, when possible, of the autopsies. The value of craniectomy in congenital idiocy due to premature ossification is upheld. The opinion is expressed that a similar surgical procedure in cases of epilepsy can not be heartily commended, at least at present. The value of thyreoid feeding in cretinism is strikingly shown in a series of three cases in which the patients were under observation for from three to six years. It certainly is a humorous notion to show portraits of the three cretins, naked, hand in hand. The influence of thyreoid feeding in obesity is recorded, and illustrative cases are cited. The report is scientific, as such a report should be.

*Transactions of the Association of American Physicians.*  
Eleventh Session, held in Washington, D. C. Vol. XI.

THE eleventh volume of these *Transactions* contains, as usual, a great many valuable papers, clinical and experimental. It is interesting to note that the blood has occupied the attention of many of the contributors, as indicated by the titles of such papers as Leucomaine Poisoning (by Dr. B. K. Rachford), Diphtheria Antitoxine sometimes found in the Blood of Horses that have not been injected with Toxine (by Dr. B. M. Balton), Parasitic Chyluria with *Filaria nocturna* in the Blood (by Dr. F. P. Henry), and A Case of Leucemia (by Dr. J. M. Da Costa and Dr. J. Sailer). Dr. L. J. Meltzer contributes a valuable experimental paper on the absorption of strychnine and hydrocyanic acid from the mucous membrane of the stomach. There is hardly an article in the volume that is not worthy of careful reading. The book is handsomely printed and the illustrations are far beyond the average in clearness and beauty.

#### BOOKS, ETC., RECEIVED.

*Twentieth Century Practice. An International Encyclopædia of Modern Medical Science.* By Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M. D. In Twenty Volumes. Volume VII. Diseases of the Respiratory Organs and Blood, and Functional Sexual Disorders. New York: William Wood and Company, 1896. Pp. 3 to 796.

*The Practice of Medicine. A Text-book for Practitioners and Students, with Special Reference to Diagnosis and Treatment.* By James Tyson, M. D., Professor of Clinical Medicine in the University of Pennsylvania, and Physician to the Hospital of the University, etc. Illustrated. Philadelphia: P. Blakiston, Son, & Co., 1896. Pp. xvi-17 to 1184. [Price, \$5.50.]

*The Cell in Development and Inheritance.* By Edmund B. Wilson, Ph. D., Professor of Invertebrate Zoology, Columbia University. New York and London: The Macmillan Company, 1896. Pp. xvi-371. [Price, \$3.]

*The Non-heredity of Inebriety.* By Leslie E. Keeley, M. D., LL. D. Chicago: Scott, Foresman, & Co., 1896. Pp. 3 to 359.

*Post-mortem Examinations in Medico-legal and Ordinary Cases. With Special Chapters on the Legal Aspects of Post-mortems, and on Certificates of Death.* By J. Jackson Clarke, M. B. Lond., F. R. C. S., Assistant Surgeon to the Northwest London Hospital, etc. London, New York, and Bombay: Longmans, Green, & Co., 1896. Pp. viii-78.

*Rodney Stone.* By A. Conan Doyle. Illustrated. New York: D. Appleton & Co., 1896. Pp. 408. [Price, \$1.50.]

## New Inventions, etc.

### A DEVICE FOR HEATING AND KEEPING HOT SOLUTIONS FOR SPRAYING THE NOSE AND THROAT.

By FRANK C. TODD, M. D.,  
MINNEAPOLIS.

ANY solution used cold in the nose is irritating to the delicate mucous membrane, and excepting in cases of epistaxis, which might be encouraged by warm applications, solutions used in the nose should be warm.

This rule does not always hold good in throat affections, as here sometimes cold applications are soothing to the inflamed parts; but in chronic affections of the nasopharynx, pharynx, tonsils, larynx, trachea, and bronchial tubes a warm spray will be found more agreeable and much more beneficial. This fact is recognized by laryngologists, but it is rare to find a physician who makes a practice of heating his solutions before spraying, owing to the fact that he must go to a great deal of trouble every time he wishes to treat a patient, wasting both time and medicine in the cumbersome procedure.

To obviate these objections I have had made and have used for a year a device such as is shown in the illustration, for the purpose of heating and keeping hot solutions for spraying.

The apparatus consists of two parts: a metal bucket, just large enough to stand upon one of the small gas stoves physicians frequently have in their offices, and a cover perforated with seven holes, each of a size to hold

the Davidson spray bottle. Fastened to this cover at the rims of these holes are hollow metal cylinders closed at the bottom. These are of sufficient length and diameter to permit the bottles to extend into the pail up to the rims on the bottles. Another hole with a screw-top cover is provided in order that the pail may be easily filled without the necessity of removing the whole cover with its contained spray tubes. The cover can be rotated and thereby any bottle may be easily procured.

When the heater is used the pail is filled with hot water, or cold water and heated. In either case it is not necessary to remove the cover or bottles. The water should be boiling hot, and, though the solutions in the bottles become almost as hot, they can be used as sprays, for when the solution becomes a spray its temperature will be much lower.

By this means the solutions will be kept warm for several hours.

The illustration would lead one to think that the spray bottles were immersed directly in the water, but this is a mistake on the part of the artist, as will be seen by the previous explanation.

The instrument is made by Messrs. Tiemann & Co. It is nickel-plated, and besides being useful is ornamental. They have also made a larger instrument with a capacity of twelve bottles, rectangular in shape (though the one described is large enough for ordinary purposes), and a small stand to rest the apparatus upon to prevent the hot pail from marring varnish or cracking glass.

304 DAYTON BUILDING.

## Miscellany.

**Notice to Medical Men and Librarians of Public Medical Libraries.**—By request, we copy the following from the *Journal of the American Medical Association* for November 21st:

1. All correspondence in relation to the enterprise should be addressed to Dr. George M. Gould, No. 119 South Seventeenth Street, Philadelphia, Pa.

2. Librarians of public medical libraries are requested to forward: 1. Accurate lists of periodicals, books, or pamphlets needed to complete their files. 2. Lists of duplicates which they will give other libraries or exchange for numbers desired. Give both volume numbers and dates of periodicals.

3. Owing to the additional labor it would involve, queries concerning the supply of desired items to private libraries can not be answered.

4. The conditions of all gifts are that the recipients shall be reputable organizations, composed of the regular medical profession; that the library shall be a public one—i. e., open for consultation during stated times to physicians generally; and that, if unbound, the periodicals and books received shall be bound and catalogued.

5. Every physician is invited to give the books and periodicals for which he has no further use to public libraries, and having no particular choice, to correspond with Dr. Gould in reference to their disposal in order to secure the greatest usefulness by the profession.

6. Send nothing before corresponding, in order that the gifts may go direct from the donors to their proper destination.

7. In order to secure the best success, physicians and librarians of other countries are invited to co-operate.

#### FOR PRESENTATION.

Librarians needing any of the following volumes (all numbers inclusive) to complete their files are requested to apply for them:

*American Journal of the Medical Sciences*, 1879 to 1890, except 1887, which is missing.

*American Medical Association, Reports and Transactions*, 21 odd volumes, 1847-8-53-55-56-66-68 to 76 and supplement volumes 1876 to 82.

*American Clinical Lectures*, vol. ii (1876).

*American Medical Journal*, 1884.

*American Medical Times*, vols. i and ii (1860-61).

*American Public Health Association Reports*, etc., vols. i to xvii.

One { *Archives of Scientific and Practical Medicine*, Vol. i (1873). *Chicago Medical Journal*, vol. xxviii (1871).

*Boston Medical and Surgical Journal*, vols. xciv to xcix (1876-78).

Braithwaite's *Retrospect*, vols. 1 to lxxxix.

*Canada Lancet*, vol. viii (1876).

*Chicago Medical Journal and Examiner*, vols. xxvii (1870); xxxiii (1876); xxxiv and xxxv (1877).

*Cincinnati Lancet*, vols. xviii and xix (1875-76).

One { *Canadian Journal of Medical Science*, 1876.

Vol. i { *London Medical Record*, part of 1873.

*Detroit Medical Review*, vol. x (1875-76).

*Gaillard's Medical Journal*, vols. xli and xlvii (1888).

*Journal of Nervous and Mental Disease*, vol. iii (1876).

*Louisville Medical News* (in one volume), vols. i, ii, and iii (1876-77).

*Medical News*, vols. xxxi to xxxix (1873-1881); also vols. xliii to xlvii (1883-85); vols. i and li (1887); and vols. — (1860-72); vol. — (1880); vols. — (1883-89); vols. — (1891-95).

*Medical Gazette*, vol. iv (1870).

*Medical Record*, iv, v, vi, vii (1869-72), xii, (1877); (1890-93).

*Medical and Surgical Reporter*, vols. xxxiv, xxxv, xxxvi (1876-77), (1885-89).

*Monthly Abstract of Medical Science*, vols. ii, iii, iv (1875-77).

*New York Medical Journal*, vols. xxii, xxiii, xxiv, xxv (1875-77).

*Obstetrical Journal of Great Britain and Ireland*, vols. iii, iv, v, vi, and vii (1875-77).

One volume of miscellany.

*Peninsular Medical Journal*, vol. i (1876).

*Philadelphia Medical Times*, 1870-1879, and 1882-1887.

*Proceedings of the Philadelphia County Medical Society*, vols. i to xv (1876-94).

*Polyclinic*, July to June, 1883-89.

*Practitioner*, 1868, July to December; 1869-73; 1877-94.

*Quarterly Epitome*, i to xx.

*Reports and Transactions of the International Medical Congress in London*, 1881. Four volumes.

*Richmond Medical Journal*, 1866-69.

*Transactions of the College of Physicians*, 1889, 1890.

*Transactions of the Medico-psychological Association*, 1895, Denver.

*Transactions of the Medical Society of Pennsylvania*, 1865-1894. Twenty-five volumes.

*Transactions of the Medical Society of Virginia*, 1896.

*University Medical Magazine*, October, 1888, to September, 1889.

#### FOR SALE.

The following volumes may be had at exceptionally low rates. Prices made upon application. These sets were bought remarkably cheap and will be sold at cost, but only to public medical libraries. Private buyers need not apply:

*American Journal of the Medical Sciences*, unbound, complete from November, 1827, to December, 1895.

*London Medico-chirurgical Transactions*, complete, in cloth, from vol. i to lxxvii, with catalogue and index.

*British and Foreign Medical Review*, vols. v to xxiv, (1836-47), and an index volume. In half calf.

*Johnson's Medico-chirurgical Review*, vols. i to xlii, including the years 1820-1843 in the old series and a continuation of six volumes in the new series, 1843-47. Cloth.

*American Journal of Obstetrics and Diseases of Women and Children*, from the commencement in 1868 to 1895. Unbound.

#### PERIODICALS REQUIRED TO COMPLETE SETS.

The Library Committee of the McGill University, Montreal, will be grateful for any of the following periodicals, which should be addressed to the Library, Medical Faculty, McGill University:

*American Journal of Obstetrics*, vol. i, No. 7.

*American Practitioner and News*, vol. xvii, Nos. Dec. to June; vol. xviii, Jan. to July.

*Anatomie und Physiologie*, Hyman und Schwalte, all before Bd. xiii, 1886.

*Annals of Surgery*, vol. v, Nos. 1, 2, 3, 4, 6; vol. vi, Nos. 4, 5; vol. vii, Nos. 1, 2; vol. viii, Nos. 1, 2, 3, 5, 6; vol. ix, Nos. 1, 2, 4, 5, 6; vol. x, Nos. 1, 3, 4, 5, 6; vol. xii, Nos. 1, 2, 3, 4, 5; vol. xiii, Nos. 1 to 6; vol. xiv, Nos. 1 to 6; vol. xv, Nos. 1 to 6; vol. xvi, Nos. 1 to 6.

*Archiv für experimentelle Pathologie und Pharmakologie*, all before 1881; Bd. xiii, Heft 2; Bd. xvii, Heft 5; Bd. xviii, Heft. 1 to 6; Bd. xix, Heft. 1, 6; Bd. xx, Heft. 1 to 6.

*Archiv für klinische Chirurgie*, all before 1876 and after 1877 to 1884; Bd. xxxiii, Heft 3; Bd. xlv, Heft 2, 3, 4.

*Archiv für mikroskopische Anatomie*, all before 1886.

*Archiv für pathologische Anatomie und Physiologie und für klinische Medizin*, von R. Virchow, all before 1881; Bd. lxxxvii, Heft 2; Bd. lxxxix, Heft 2, 3; Bd. cii, Heft 3; Bd. cviii, Heft 1.

*Archives of Surgery*, all before 1890.

*Berliner klinische Wochenschrift*, all before 1880; vol. lxxxviii, Nos. 1 to 40.

*Brain*, vol. ix and from vol. xi.

*British Journal of Dermatology*, all before 1891; vol. vi, No. 5.

*Canada Lancet*, vol. i, vol. ii; vol. xxiii, January, February, July; vol. xxiv, October; vol. 26, September, October, November, December; vol. xxvii, October, January, March, and June.

*Canada Medical Record*, vol. ii, No. 4 and index; vols. xiii to xviii, want index; vol. xix, Nos. 6, 7; vol. xx, Nos. 1, 2; vol. xxi, Nos. 2 to 12; vol. xxii, Nos. 1, 2, 3, 4, 5, 7, 8, 9, 10, 11.

*Centralblatt für Bakteriologie und Parasitenkunde*, Bd. xiv, No. 15; vol. x, No. 9; vol. xi, No. 25.

*Centralblatt für Chirurgie*, all before 1886.

*Climatologist*, vol. i, Nos. 1, 5; vol. ii, No. 5, and all after.

*College of Physicians, Transactions of the*, all before 1879.

*Congress of American Physicians and Surgeons, Transactions of the*, all before 1891.

*Deutsches Archiv für klinische Medicin*, vol. liv.

*Deutsche medicinische Wochenschrift*, all before 1886; vols. 1891-93.

*Dominion Medical Monthly*, 1893, No. 6; 1894, No. 6.

*Edinburgh Medical Journal*, The, vol. xvi; Dec., 1894; April, 1895; June, 1895.

*Gazette médicale de Montréal*, vol. i.

*Gynecological Journal*, all after 1872.

*Gynecological Transactions*, vols. iii, and all after 1881.

*Guy's Hospital Reports*, series 3, vols. xvi and xxv.

*St. Bartholomew's Hospital Reports*, vols. xxvii, xxviii.

*Royal London Ophthalmic Hospital Reports*, vol. v, part iii; vol. x, part ii; vol. xi, part iii; vol. xii, part iii, vol. xiii, index.

*Jahresbericht über die Fortschritte der Anatomie und Physiologie*, Bd. xii.

*Jahresbericht über die Leistungen und Fortschritte in der gesamten Medicin*, all before 1882; Bd. ii, Abth. 3.

*Journal de l'anatomie et de la physiologie*, all before 1886.

*Journal of the American Medical Association*, vol. ii, Feb. 2-16, May 24; vol. iii, July 26, Sept. 20, Oct. 11, 18, 25, Nov. 1; vol. iv, Jan. 10, 24, April 25; vol. v, July 18, Sept. 12, 19, Oct. 3, Nov. 28, Dec. 19; vol. vii, Jan. 1, March 19, April 9, 16, 23, 30, May 7, 21, June entire; vol. ix, July 9, 16, 23, Aug. 6, 13, 20, Sept. 10, Oct. 8, Nov. entire, Dec. 3, 10, 17; vol. xi, July 21, Sept. 8, Oct. 6, Nov. 24; vol. xii, Jan. 12, Feb. 16, 23, April 27, May 4, June 8; vol. xiii, Aug. 10, 24, 31, Sept. 7, Oct. 26, Nov. 9, Dec. 7, 14; vol. xiv, Jan. entire, Feb. 1, 22, March 8, 15, 22, April 19, 26, May 24, 31, June entire.

**A Case of Rattlesnake Bite, with Recovery after the Continuous Application of a Tourniquet for Twelve Hours.**—Dr. William W. Ashhurst, of Chihuahua, Mexico, relates the following case in the November number of the *International Medical Magazine*: The patient, a boy fourteen years of age, was bitten on the third finger of the right hand by a small rattlesnake on the evening of July 16, 1896. A few minutes after the occurrence of the accident, some member of the family applied a Spanish windlass ligature to the arm just below the axilla. This remained in position about twelve hours, when it was removed by a physician.

The patient was first seen by the author on the morning of July 17th, more than twenty-four hours after the accident. He found him in a condition of profound depression. Neither the radial nor the axillary pulse of the affected arm could be felt at all, owing to the great swelling of the limb, and the pulse of the left radial artery was so weak that it was almost impossible to count it. The right arm was enormously swollen, and the skin of a brawny consistence. The injured finger did not seem more swollen than the others of the same hand. A shrill systolic murmur was perceptible over the aortic cartilage, which was probably of hæmic origin.

As the arm was warm, and there was present some feeble capillary circulation in the fingers, Dr. Ashhurst concluded, in order to soothe the intense pain of which the patient complained, to try the effect of a cooling lotion, and ordered therefore, locally, lint soaked in lead-water and laudanum, to be renewed every hour, and internally, alcohol, carbonate of ammonium, digitalis, and nux vomica, with liquid diet, and with rest in the recumbent posture strictly enforced.

On account of the length of time that had elapsed since the injury, the author deemed it useless to apply any local antidote, as he believed the poison to be already thoroughly distributed through the arm; and at the same time it seemed most probable that, on account of the feebleness of the circulation in the injured limb, the poison would enter the general circulation very slowly, thereby rendering further application of the tourniquet not only dangerous, but useless.

By evening, continues the author, the pulse was stronger, and the patient expressed himself as greatly comforted by the lead-water and laudanum. On the following day, July 18th, the patient's general condition had further improved somewhat, but the œdema had spread to the neck and chest. By July 19th it had extended downward as far as the crest of the ilium on the right side, completely around the neck, and across the chest as far as the left axilla. The skin was discolored, purple, and blackish in patches over the arm, side, chest, and abdomen. At this time the brawniness of the arm was disappearing, and the radial pulse could be felt. The patient was now put upon the use of Basham's mixture and nux vomica, and continued to improve.

By July 25th all the swelling and discoloration had disappeared, the heart murmur could no longer be detected, and the patient could use the right hand and arm, although they were still somewhat stiff and painful on motion. He was now allowed to get up and go home,

and subsequently reported himself, perfectly recovered, on August 21st.

**Kleptomania; the Case of Mrs. Castle.**—In an editorial on this subject in the *British Medical Journal* for November 14th, the writer refers to several points of unusual interest.

The plea of insanity or irresponsibility, he says, was raised at the trial. Probably there is no class of cases in which the duty of the expert is more onerous and more often misunderstood than these. The general cry is that there is one law for the rich and another for the poor; or that kleptomania is a rich man's disease. This is true to a great extent, for the simplest definition of the disease is causeless or unreasonable stealing, and the chief evidence of its being unreasonable is that the thief is rich and does not require the articles stolen. Mrs. Castle was shown by the medical witnesses to have had uterine trouble, which dated back from her confinement, and there was evidence that she had suffered more or less ever since, and had been very hysterical.

The writer states that Dr. Grigg gave evidence that her uterus was in a very abnormal condition, and was in such a state as is often met with in hysterical and unstable nervous states, and that Dr. Savage, who examined her in the prison during the remand, gave evidence that she was very hysterical and nervous, while the strongest witness of all was the prison surgeon, Dr. Scott, who had her constantly under his observation. The evidence of nervous instability was carried back by Dr. Gilbert to some time before the criminal acts. Thus, he says, there was a strong unbroken chain of testimony that the woman was abnormal as far as her nervous state was concerned. It has been pointed out both by prison surgeons, such as Dr. J. Baker, and by alienists that such people provide most of the kleptomaniacs.

It is now well recognized, the writer goes on to say, that with hysteria there may be an endless and incalculable series of strange and purposeless acts, and among these theft is not uncommon; young women, women at the menopause, and those suffering from menstrual irregularities are untrustworthy in many ways. Mrs. Castle, then, was of the class described. The nature of the thefts, too, is important, for it is known that in many cases there is an insane habit of collecting similar objects, and, as in this case, making no use of them. In this instance there were innumerable eye glasses, opera glasses, and fur tippets, besides odds and ends of great variety. The most unreasonable things taken were those of little value, such as plated toast racks, with the hotel mark on them, as well as towels of no real value.

The writer believes that, taking into consideration the nervous symptoms in the woman, associated as they were with uterine troubles, and also the character of the articles stolen, justice has been done in allowing her to go free, notwithstanding the apparent cunning shown in the stealing.

**Sulphonal Poisoning in a Case of Melancholia Agitata.**—The following case is related by Mr. F. P. Hearder in the *Lancet* for November 14th:

A man, forty-three years of age, single, of steady habits and with a good family history, four months previously to his admission on May 2, 1896, to the Wakefield Asylum had hurt the back of his head in an accident; he suffered much from shock and had been very nervous since. Three weeks before his admission he cut his throat. His physical state on admission was as

follows: His height was four feet ten inches, and his weight a hundred and twenty pounds. He was fairly well nourished. He had a cut across the front of his throat an inch and a half in length, which opened into the trachea and healed by granulations. When he spoke, a peculiar buzzing and whistling sound was produced by the air escaping through this opening. His hair was black and his complexion was sallow. The pupils were unequal, the right being more dilated than the left; the left pupil reacted more perfectly. His knee-jerks were exaggerated and there was slight ankle clonus. His superficial arteries were thickened and tortuous; the heart's action was irritable and irregular, and the sounds were accentuated, but there was no bruit. In the urine there was a copious mucous cloud; it was acid, of specific gravity 1.022, and contained no albumin or sugar. His mental state on admission was that of agitated or motor melancholia. He had a dejected and lacrymose expression and he had aural and visual hallucinations and delusions that harm (murder, etc.) was happening to his mother and sister; he cried and prayed for their safety. During the next few days he continued restless, sleepless, needed forcible feeding, and was constantly attempting to tear the bandage off his throat, and required continual supervision. A mixture of bromide of potassium with chloral hydrate was exhibited with no good effect. Sulphonal was then tried (fifteen grains three times a day), administered in a warm drink, apparently with marked good effect, as he took his food better, slept well at night, and was less restless during the day. On the fourth day his gait was ataxic and his expression and movements were like those of a drunken man. On the sixth day the urine—which, as is usual in patients taking sulphonal, was being carefully watched—was noticed to be becoming scanty and highly colored. The sulphonal administration was at once stopped and the urine examined. It contained no blood and no albumin. On the following day there was marked oliguria, about five ounces of urine having been passed in the twenty-four hours. The urine was of about the color of porter which had been shaken; there was no deposit, it was acid, and of specific gravity 1.015. The amount of albumin was exceedingly copious, the urine on being boiled becoming almost solid. The patient was in a somewhat soporose state; there was slight oedema of the eyelids, but no swelling of the legs and ankles. The pulse was quiet and the temperature about normal. He was kept recumbent and a saline purge was administered, a diuretic mixture containing citrate of potassium and acetate of potassium being given, with diluent drinks, milk and soda-water, and barley-water. On the following day the urine was still somewhat scanty, highly colored, acid, and of specific gravity 1.020, but it contained no blood or albumin. The patient was better and took food (fluid and semifluid) freely. Since then he has made considerable physical and mental improvement, but continues depressed. Several subsequent examinations of his urine have revealed nothing abnormal.

With the exception of a few cases of post-influenzal debility where single doses of sulphonal have been followed by toxic effects, says Mr. Hearder, all cases of sulphonal poisoning have been after long-continued use of the drug, the symptoms usually being lethargy, giddiness with digestive disturbances, anorexia, constipation, occasionally diarrhoea and vomiting, and hematuria, pyuria. A German observer, he says, has also noted ischuria, oliguria, and sometimes albuminuria. Professor Stokvis, on experimentally administering sul-

phonal to dogs and rabbits, found "it was only when the drug was pushed to a fatal termination that albumin appeared during the last days of life." In this case the dose was comparatively small and the toxic effects acute. The author considers that it is a good example of the necessity of training attendants and nurses to note the urine of every patient who takes sulphonal.

**A Case of Simple Fracture without Displacement of the First Phalanx of the Great Toe from an Indirect Cause.**—At a recent meeting of the Association française de chirurgie, a report of which is published in the *Gazette hebdomadaire de médecine et de chirurgie* for November 12th, M. Inglessis said that, as simple fractures of the great toe were rare, especially those from indirect violence, which were not generally accompanied by displacement, they might, because of this fact and the absence of deformity, be overlooked on a superficial examination. If they were unrecognized or neglected, these fractures might be followed by serious results, such as enormous and threatening swelling, with considerable ecchymosis, and blebs. This, he said, had occurred in a case which had come under his observation. The patient had suffered for three months with a fracture which had not united or been reduced, and he had been obliged to practise tenotomy of the long extensor of the great toe, and to immobilize the foot in order to maintain reduction and to obtain consolidation of the fracture. It might easily be understood, he said, that defective consolidation resulting from the lack of proper treatment might impede walking or lead to the necessity of wearing a particular kind of shoe.

**Contract Practice in California.**—Under date of November 18th, Dr. Lincoln Cothran, of San José, secretary of the Associated Physicians and Surgeons of Santa Clara Valley, writes to us as follows:

"We ask you to give publicity to this letter and accompanying resolutions, to the end that in all communities afflicted with the pestiferous practice of lodge doctoring, physicians may be encouraged to assert their independence through organization.

"Here, in Santa Clara County, Cal., containing seventy thousand population, all the physicians of the county, numbering a hundred and twenty-four, have entered the compact that has ridden us of a slavish evil, and wrought independence and freedom for the practitioners of medicine. Investigation shows that medical compensation for lodge work averages about fifteen cents on the dollar.

"Even respectable lodge physicians feel a sense of degradation in giving their services for fifteen cents on the dollar, and the ever-increasing spread of these alleged charitable institutions is absolutely destructive to the business of other physicians.

"The main incentive of the persons who band themselves together in lodges is to get cheap doctoring; they are willing to take but not to give. They belong to protective unions, and the same right should not be denied physicians. Ninety-nine per cent. of these people are able to pay reasonable fees to physicians, but will not do so as long as a few doctors in every community for the sake of immediate gain can be induced to stand as driven guys to the lodge politicians. No preacher or lawyer would give his services to these people for fifteen cents on the dollar. No grocery store or merchandise firm would contract to supply these lodges with goods at fifteen cents on the dollar of actual worth.

"The remedy indicated in the subjoined resolu-

tions is simple, and manifestly efficacious, depending upon the personal honor and free will of those concerned. Where one doctor temporarily profits by contract work the business and ethical rights of fifty others are violated; hence an overwhelming *esprit de corps* is created among physicians which will sustain a strict observance of the pledge."

The agreement is as follows:

"Whereas, Rendering professional services at a stipulated fee per capita per annum is derogatory to the dignity of the medical profession, we, the undersigned physicians and surgeons of Santa Clara County, California, enter into the following agreement:

"First. We mutually, jointly, and individually pledge our word of honor not to enter into any contract or agreement, or renew any existing contract or agreement, either written, verbal, or implied, to render medical or surgical services to any lodge, society, association, or organization.

"Second. We will not render medical or surgical services to the members of the above-mentioned bodies for less compensation than we charge the general public for similar services.

"Third. This agreement shall not be construed to affect existing contracts between physicians and surgeons and the above-mentioned bodies.

"Fourth. These pledges shall take effect and be in force for a term of three (3) years from and after May 22, 1896.

"This agreement shall not apply to hospitals and purely public charitable institutions."

It is signed by the physicians of San José, Santa Clara, Los Gatos, Palo Alto, Mayfield, Mt. View, Morgan Hill, Gilroy, Saratoga, Agnews, Campbell, Milpitas, and College Park.

**The Late Dr. Thomas H. Burchard.**—The Northwestern Medical and Surgical Society has adopted the following resolutions:

"Whereas, It has pleased God to take away Dr. Thomas H. Burchard, distinguished by twenty years of active and faithful membership in the Northwestern Medical and Surgical Society of New York; and,

"Whereas, Our hearts are touched with a great sorrow by the suddenness of his decease; therefore

*Resolved*, That we desire to place on record an expression of our esteem of our late colleague, who had endeared himself to us by a long line of friendly and generous offices; that we desire to commemorate his devotion to the medical profession, exemplified in so high a degree by his many contributions to this and to other medical bodies, and by his acknowledged skill as a surgeon; and that we realize in the life of our friend the large equipment of mind and body essential to the success of a true physician.

*Resolved*, That a copy of these minutes be sent to the bereaved wife and sons and to the near relatives of our late colleague, to whom we extend our sincere sympathy in their great affliction.

*Resolved*, Further, that a copy of these resolutions be sent to the various medical journals of New York for publication.

For the society,

[Signed.] EDWARD S. PECK, *Committee*.

**The Loomis Memorial**, which is one of the buildings that make up the Loomis Sanitarium, in Liberty, Sullivan County, N. Y., was dedicated by Bishop Potter on Friday, November 20th. The cost of the building has been borne by Mr. J. Pierpont Morgan, of New York.

## Lectures and Addresses.

### LECTURES ON ANGINA PECTORIS AND ALLIED STATES.\*

By WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

#### LECTURE VII.—DIAGNOSIS, PROGNOSIS, AND TREATMENT OF ANGINA PECTORIS.

**DIAGNOSIS.**—One must be a professional Ulysses in craft and wisdom not sometimes to err in estimating the nature of an attack of severe heart pain. There is no group of cases so calculated to keep one in a condition of wholesome humility. When you jostle against a hale, vigorous specimen of humanity, who claps you on the back and says, "The deuce take you doctors! I have scarcely yet got over my fright," you would like to forget that five years before you had almost signed his death warrant in a very positive diagnosis of angina pectoris vera. On the other hand, Mr. X. has left you with the full assurance that his cardiac pains are due to overwork or tobacco, and you have comforted his wife and lifted a weight of sorrow from both by your most favorable prognosis. With what sort of appetite can you eat your breakfast when, a week later, you read in the morning paper the announcement of his sudden death in the railway station? Or take another aspect—poor Mrs. Doe has gone softly all these years in the bitterness of her soul since you took that grave view of her vasomotor or hysterical angina!

As a rule you will have little or no doubt as to the existence of angina. The chief difficulty is in deciding upon the functional or organic nature of the trouble. There are, however, extraordinary cases of recurring pain about the heart, of terrible severity, the nature of which may be very obscure. The following is one of the most remarkable cases of this kind which I have met:

J. H. McC., aged forty-nine years, seen April 28, 1887, complaining of attacks of terrible substernal pain. He was a large, active man, weighing a hundred and ninety-five pounds. With the exception of a chancre at his fifteenth year, which was followed by an ulcer on the leg eight months afterward, and typhoid fever three years ago, his general health has been good.

Twelve years ago (1875) he consulted Dr. Weir Mitchell for the following symptoms: Every morning, about one o'clock, he was aroused from sleep with severe pains in the lower part of the chest, beneath the sternum. At first the attacks occurred every night, and then at intervals of four or five days. The pain was not like a cramp or a spasm, but dull and severe, intense enough to make him get up and walk the room. For nearly ten years the attacks made his life a burden. They ceased abruptly in 1885, since which date he has been quite well until March 28th of this year. He now has the attack every day about 1 A. M. He goes to bed

at ten o'clock and falls to sleep comfortably. Usually about 1 A. M., sometimes at three or four o'clock, he is aroused by a fixed pain beneath the sternum between the fourth and fifth costal cartilage. It is never transmitted down the arm; he is never doubled up with it, nor does he turn pale or sweat. He occasionally belches wind during the attack. The pain at times is so severe that he has to take an anæsthetic. Thus on the 29th he awoke at 3.30 A. M. in terrible agony, and had to take ether. He slept until after five o'clock, when the pain again came on and persisted until noon. He says he has noticed that it is often worse after the rest of Sunday. The examination was entirely negative. The arteries were not stiff; the heart's action was regular; the aortic second was not accentuated. He winced a little on deep pressure just above the ensiform cartilage. The urine was normal.

He had taken iodide of potassium previously without, he thought, any benefit. Considering, however, the history of syphilis, I insisted upon his taking it again. I heard from him on several occasions for a year or so, and there was not very much change in his condition. I have since lost track of him.

A case somewhat similar to this is reported by Dr. Randall, of Decatur, in the *Medical News* for March 11, 1893. The patient was a healthy man who had remarkable seizures of agonizing pain in an area twelve inches in diameter over the heart, which recurred nightly from August 1st to December 16th unless he remained awake and out of bed. The patient was a self-possessed, unimaginative man, and had never had similar attacks. The pain was sometimes greatest in the epigastrium, sometimes in the præcordium, and with it there were tingling and numbness in the arms, and a sense of suffocation. There was no dyspnoea or asthmatic breathing. The patient could avert the attack every night by vigilance. It is difficult to decide upon the nature of such cases.

The important elements in diagnosis are the sex, the presence of cardio-vascular disease, and the phenomena of the attack.

The extreme rarity of true angina in women is always to be borne in mind, even when the general features of the case are most suggestive. Such an instance, for example, is the following:

Mrs. R., aged forty-two years, seen October 25, 1894. She has always been a healthy woman, but has had much trouble and worry. Her husband had attacks of angina pectoris, and died a year ago of heart disease. Her mother died in an attack of angina pectoris three years ago. For nearly a year she had been unable to rest comfortably on her left side, and had been much troubled with pains about the heart, which were sometimes of great severity, and were then accompanied by a feeling of numbness in the left arm extending to the fingers. Neither diet nor exercise seemed to make any difference, and she never had dyspnoea. Sometimes the whole of the left side, including the neck, would feel stiff and sore. Though she had been free for a few days from the sensations of pain, she had not within the past year had a week of complete intermission. She had evidently worried very much about it,

\* Delivered to the Post-graduate Class, Johns Hopkins Hospital.

and dreaded consulting a physician, lest she should be told she had the disease of which her mother and husband had died.

The patient was a healthy looking woman. The pulse was quiet, without increase in the tension, and the arteries were not stiff. There were no signs of hypertrophy or dilatation of the heart; the sounds were normal. The urine had a specific gravity of 1.018, and was free from albumin and tube casts. I have seen this patient on several occasions during the past two years, and her condition has improved very much.

There are cases, too, in which hysterical angina occurs in women with aortic valve disease. The only instance of the kind which has come under my notice is the following:

Mrs. K., aged thirty-eight years, seen February 24, 1890. The patient was an unusually bright, able woman, who had for several years lived under a serious mental strain. She had severe rheumatism as a child, and she had been told by several physicians—among others the late Dr. Austin Flint and Dr. Da Costa—that she had heart disease. The first serious attack of pain about her heart was two years ago at a hotel, when she fainted. During the past three months she had had eight or ten attacks. They usually came on when she was worried or very anxious. She got cold; the pains began just under the left breast and shot into the arm and up the neck. During the attacks her physician said she had often been quite hysterical, tossing herself about, and talking in a very incoherent way. The apex beat of the heart was a little outside the normal position; the aortic second sound was intensified, and at midsternum, opposite the third costal cartilage and along the left border of the sternum, there was a soft diastolic murmur. The pulse was regular, a little jerky; the vessel wall was a little firmer than normal. When I saw her she was having pretty frequent attacks, and was very nervous and hysterical. After removal from her home surroundings, with rest and quiet, and a course of tonics, she improved very greatly. After my examination I made the following note: "Do the attacks represent true or hysterical angina? That there is a strong neurotic element is undoubted, but the presence of aortic insufficiency, a condition which had been recognized by several physicians some years ago, makes the diagnosis a little dubious." I have seen the patient at intervals during the past six years, and she has had no recurrences of the attacks, and has been in excellent health.

The extreme rarity of true angina in women must always be borne in mind, and also the infrequency of its association, as noted in Lecture II, with mitral-valve disease. Flushes, paræsthesiæ, and various nervous or hysterical manifestations, and particularly the vasodilator type of phenomena, suggest strongly pseudo-angina, even though a loud mitral murmur be present. I saw with Dr. Clark, of Kingston, Ontario, a very puzzling case of this kind, the notes of which I have unfortunately mislaid.

In men, while true angina may coexist with apparently normal cardiovascular condition, in a very large proportion of all cases there are signs of greatly heightened blood pressure, or of sclerosis of the arteries, with

a ringing metallic aortic second sound; sometimes only the signs of a weak heart. In men under the age of forty the existence of syphilis should be suspected, as a by no means inconsiderable number of cases result from an aortitis, causing great swelling of the intima and narrowing of the orifices of the coronaries.

In men, too, the question of tobacco has always to be considered, as recurring paroxysms of really maximum intensity may be due to persistent smoking or chewing.

In determining between a true and a false angina, the phenomena of the attack offer most valuable differential criteria. The character of the pain in pseudo-angina, while it may be very severe, rarely has the agonizing quality of true angina, and is seldom, if ever, associated with the sensation of impending death. Patients more often complain of a sense of fullness and distention in the heart. The seat of the pain may be in both identical, and I do not think that much stress can be laid on the point that in pseudo-angina the maximum pain is more over the heart and toward its apex, while in the organic disease the chief seat of the pain is toward the base of the heart and over the aorta. You must remember that in true angina the seat of the pain may be entirely away from the chest, and may be, as in Lord Clarendon's father, at the inner aspect of the arm, or about the wrist, or in rare instances confined to the side of the neck, or even to one testis. While in both forms the pain may radiate to the side of the neck and to the left arm, in pseudo-angina the associated nervous sensations are apt to be much more widespread. There may be numbness and tingling in both extremities, or prior to the onset there may be a feeling of pins and needles in the hands and feet. The vasomotor phenomena are apt to be much more pronounced in pseudo-angina. The attack may be preceded by flushes, by a sensation of great oppression in the back of the neck or head, and then before the onset of the cardiac pain, not with it or following it, there is coldness of the extremities and sometimes a pronounced tremulousness amounting to what is popularly called a nervous chill. Sweating, combined with the pallor, is not so common in pseudo-angina. The paroxysms of false angina rarely have great abruptness of onset, but are preceded by various nervous and hysterical features.

The attitude in angina pectoris vera is one of its most characteristic features. The patient rarely can stir from the spot in which he is attacked. In the hysterical and neurasthenic angina there is often great jactitation, seldom immobility. The patient tosses about on the bed with noisy exclamations of pain, or may walk the floor screaming loudly.

The duration of the attack in pseudo-angina is usually more prolonged, lasting perhaps an hour or more. As I have already mentioned, it occasionally happens that even in the true angina, as in Mr. Sumner's case, the patient is able to walk about, finding relief in moderate exercise during the attack.

And, lastly, among the important points of diagnosis are the circumstances which promote the attacks. In true angina the patient can nearly always fix upon some provocation, as muscular effort, mental irritation, an attack of indigestion; whereas in pseudo-angina the attacks are much more apt to occur spontaneously, and rarely are excited by effort.

It must be acknowledged that the diagnosis is not always so easy as you might suppose from any glib summary of differential signs; thus just the other day I was consulted by a practitioner from one of the large Western cities, in whose case the existence of certain well-pronounced coincident nervous phenomena seemed alone to clinch the question of diagnosis. The patient was aged about fifty, a strong man, of strong stock, who had been engaged in large general practice for more than twenty-five years. He had never had syphilis, and had been temperate in the use of alcohol and tobacco; somewhat intemperate in coffee. He had lived a life of a good deal of tension, but had been very well, with the exception of at intervals rheumatic and neuralgic pains. He had never had gout. Two years ago, after a long and tiring drive, he went out one evening to make a visit, and while at the patient's door had a very severe attack of pain about the apex of the heart, which lasted for a minute or two, and which frightened him very much. The next day at dinner he was seized again, but the pain was scarcely so intense; it was duller and more boring in character. He suffered all night, and in the morning had to take a hypodermic injection of morphine. He had no faintness, the circulation was not involved, and there was no sense of impending dissolution. He felt very weak and used up for nearly a week. He had no return whatever of the pain until last October. He had been working very hard, and had lost a great deal of rest. Then he had the pains at intervals, while he was driving, at the table, when walking, or in bed. They were never very severe, and did not interfere with his work. They were chiefly about the apex of the heart, not beneath the sternum. They radiated down the arms, particularly the left, but he has had pains in both arms as far as the wrists, with numbness, and on several occasions he has had pain and numbness in the left arm without the pain about the heart. These attacks persisted on and off all through the winter, until about two months ago. He then had an attack of influenza with fever, and since then he has had a great deal of nervous palpitation of the heart, particularly on emotion, or if his stomach is full. He does not appear ever to have had a severe agonizing attack with sweating and a sense of impending dissolution.

Certainly in a man of over fifty, though his heart was normal, and his arteries not specially sclerotic, and the pulse tension very little raised, such attacks were, to say the least, suggestive of true angina. But on going into his case more fully two circumstances developed, which were, I think, of much moment, in-

dicating probably that he was of a more neurotic temperament than he was willing to confess. Between three and four years ago, when overworked and worried, he had extraordinary attacks of slight spasm of the glottis, which would come on while he was taking food, or at any time if he was very excited. It would be relieved with a deep, noisy inspiration almost like child-crowling. These attacks passed away, and he has not had them since. But last summer his wife says that he had the most extraordinary attacks of spasm of the gullet, recurring at every meal for nearly six weeks. At the first attempt at swallowing, either of liquids or of solids, there would be a sudden interruption, which he describes as a sort of spasm of the gullet, and he had to wait several minutes for it to pass off before he could take another mouthful. This patient was very nervous and apprehensive that he had true angina, and yet I think the existence of well-marked oesophagismus and of laryngeal spasm three or four years ago are circumstances which suggest a diagnosis of pseudo-angina.

PROGNOSIS.—One of the most distinguishing features of true angina is a consciousness on the part of the patient, in his anguish of mind, that the very citadel of life has been approached. In a severe, long-continued paroxysm all desire of recovery may be absent in the dread lest he should have again to endure the agony. Subjects of the disease may truly be said to stand in jeopardy every hour, yet it is astonishing with what equanimity the affliction is endured. Charles Sumner said: "This treacherous disease produces in my mind a positive uncertainty when I go out of my house whether I shall ever enter it again a living man." The duration of the disorder is most uncertain; there are notable cases, such as John Hunter, in which the attacks have recurred at intervals for twenty or more years.

Recovery is quite possible, and there are instances in which the attacks disappear entirely. In June of last year, in consultation out of town about a case of heart disease, Dr. — mentioned to me his own case as one of exceptional interest. He was a man of fifty years of age, and had been in very active practice. Twenty years ago, he had been for nearly a year a terrible sufferer with angina. He was under the care of the late Dr. Donaldson, who regarded the attacks as genuine, as there was also well-marked aortic insufficiency. The patient has remained perfectly free for twenty years.

I saw in November, 1886, with Dr. J. William White, a naval officer, aged forty-six years, who had had severe attacks of angina associated with immobility and a sense of great *angor*. He was a powerfully built man, who had lived well and had taken a great deal of heavy exercise. The pulse tension was increased and the aortic second was accentuated. He had been a heavy smoker, but had not had syphilis. He had kept a very accurate account of the attacks, and he had between Oc-

tober 11, 1886, and August 11, 1887, two hundred and thirty-nine, most of them slight, but some of terrible severity. From the date mentioned to the present he has remained perfectly well, and attributes his recovery largely to the use of the iodide of potassium. He stopped smoking at the time of the paroxysms, but has resumed it since without any detriment.

In a disease so notoriously uncertain as true angina, the prognosis must necessarily be most guarded. Fortunately, as I have already said, the character of the attack is such that the patient is very well aware of the extreme hazard of his state. Of the important elements in prognosis, the following are to be considered:

The frequency and severity of the attacks. Recurrence at short intervals of paroxysms of great severity, induced by slight exertion, is of ill omen, particularly if with them there are marked cardiac arrhythmia and signs of dilatation.

The existence of valvular disease does not in itself materially aggravate the prognosis. A large majority of the worst cases of angina show no signs of heart lesions. The existence of aortic disease renders the patient, of course, much more liable to myocardial changes and dilatation and the other consequences of progressive failure of the muscular power. The following is a remarkable instance of good health, even vigor, for years with aortic-valve disease and angina of ten years' duration:

Mr. X., aged fifty-one years, Holbrook, Maryland, consulted me June 10, 1895. His general health had always been good. So long as he could remember he had had heart trouble; he had been short of breath on exertion, and had been conscious, as he expressed it, of a sort of grinding in his chest. When a child he had attacks of extensive blotches on the skin with gastrointestinal pain (Henoch's purpura). He had rheumatism when twenty-two, but no swelling or redness of the joints. With care he has been able to get about and has lived very comfortably, though he has never been able to do heavy work.

He looked pale, a little thin, and had a suggestive cardiac *facies*; there were no signs of any swelling of the joints. There was an inguinal hernia on the right side. The apex beat was in the fifth and sixth spaces just outside the nipple line. There was a large area of cardiac impulse. There was a loud systolic murmur at the apex region, propagated to axilla and loudly along pectoral border. It increased in intensity toward the left margin of sternum. In the whole apex region there was almost silence in diastole, perhaps a faint rumble, and at the apex there was a slight systolic shock. The systolic murmur became very loud over the sternum, and attained a maximum intensity at the second right costal cartilage, where it was rough, harsh, vibratory, and was propagated with great intensity into the vessels. Along the left margin of sternum and as low as the ensiform cartilage there was an extremely soft diastolic murmur. There was no pulsation to be felt in the sternal notch. The pulsation in the superficial arteries was visible; the vessels were a little stiff. The pulse was 100, not collapsing, of medium volume, and gave one the impression of effort.

He had his first attack of angina ten years ago, coming from Chicago. Two years subsequently he had another attack, and had to have morphine. He has had six or seven attacks altogether, the last one seven days ago as he was getting out of bed. On each occasion there has been a single attack; morphine alone controls them.

Ten years ago he evidently had an attack of cardiac breakdown, with great shortness of breath. Subsequently, for three years, he took ten drops of the tincture of digitalis three times a day, without missing, he thinks, a single dose. During the attack he feels very badly; there is immobility and agonizing pain in the chest, he feels as if he was going to die, and he sweats profusely.

A word or two upon an ethical problem which is often very perplexing—viz., What is your duty in the matter of telling a patient that he is probably the subject of an incurable disease? I can give you no hard-and-fast rule; the temperament of the individual himself, his associations and responsibilities, your own convictions as to the seriousness of the condition—all these must be carefully weighed. The question is somewhat theoretical, since in reality the necessity does not often arise. The announcement has already been made, for no man suffers the anguish of a severe paroxysm of angina without a consciousness of the nearness of the Angel of Death. We are sometimes, I confess, placed in positions of the utmost delicacy, since a man may have not the slightest intimation of his parlous state, and you may become aware of the urgent necessity that he should make proper arrangements to protect his wife and children. In such a case a quiet hint as to the uncertainty of the outlook in heart and artery disease may be enough to set him a-thinking; or, in the case of an "even-balanced soul," the whole question may be discussed frankly. One thing is certain: it is not for you to don the black cap, and, assuming the judicial function, take hope from any patient—"hope that comes to all"—and we may dwell with advantage on the aspects of John Hunter's case rather than on those of Thomas Arnold.

(To be concluded.)

## THE PRESENT NEEDS AND FUTURE DEMANDS OF ORTHOPÆDIC SURGERY.

A PORTION OF AN ADDRESS DELIVERED BEFORE THE TRUSTEES OF THE NEW YORK ORTHOPÆDIC DISPENSARY AND HOSPITAL UPON THE OCCASION OF THEIR TWENTY-NINTH ANNUAL MEETING.

Held November 16, 1896.

By NEWTON M. SHAFFER, M.D.

GENTLEMEN: As I rise to address you this evening the new hospital building approaches completion. Recently remodeled and much enlarged, it is fully equipped in every important respect for modern orthopædic work.

A year ago we were deeply in debt. The ordinary dwelling house adjoining your property on the east, unfitted for hospital use, had been purchased. We were

without means to erect a suitable hospital structure in its place. To-day, through the kindness of friends, a new fireproof hospital building, as yet not wholly paid for, stands in the place of the property which we purchased. Aided by this additional building, we find that our capacity for hospital patients has been increased one third; we have made various changes in the Sloane pavilion and in the older hospital structure; an elevator has been introduced; we have a complete Röntgen-ray apparatus, a modern operating room has been added to our equipment, and the three original buildings comprising our now consolidated hospital represent all that the most earnest critic could demand in orthopædic work. It matters but little where the examination commences, whether in the shop, where the most intricate and delicate apparatus for the treatment of deformity can be made; or in the domestic department, where all the modern improvements have been introduced, the progress upward from story to story develops a careful economy of space, with a liberal allotment of room for both the dispensary and hospital.

The dispensary is especially adapted to the needs of the outdoor patients, who crowd the reception and treatment rooms daily. It is on this floor that the X-ray room has been placed, and it is here also that the interesting work of the neurological department has been located. Nearly the whole first floor of the three buildings comprising our remodeled hospital is given up to dispensary work.

On the second floor are located the rooms for the administrative work of the hospital, the children's dining room, and the operating room—the two latter being rooms that would attract attention in any hospital.

Six wards, accommodating seventy-five patients, occupy the third and fourth floors, and everything has been done to make these wards bright, attractive, and aseptic, while the problem of ventilation has received its full share of attention.

The fifth story contains the children's play room, the roof garden, and rooms for nurses, while, at a remote point and unconnected with the rest of the house, and with an entrance from an open roof only, there is an isolated ward with suitable sanitary adjuncts, for suspected acute infectious and contagious diseases.

This, in brief, is a description of your completed building. The more one studies the arrangement of the various parts of the building and notices how completely the compact whole represents the needs of a modern and progressive orthopædic hospital, the more the friends of your work must be satisfied.

Modern orthopædic work demands all that you have given your medical staff. The theories of a few years ago regarding the causation of tuberculosis have become demonstrated facts. The light which modern bacteriological investigation has thrown on the various morbid processes which enter into the question of the production of certain chronic deformities is no less important

to the orthopædic than to the general surgeon. In treating these deformities from the operative standpoint, the orthopædic surgeon needs the same training as the general surgeon, and the same aseptic and general surgical care should be exercised, for example, in opening a simple abscess connected with a diseased joint as in operating for an acute appendicitis. But while the general surgeon covers a wide operative field, the orthopædic surgeon finds, in his work, a more limited operative field. The latter, however, should be no less a surgeon because he operates in those cases only which require special orthopædic care after operation. To extend the operative field of orthopædy beyond this point is to break down the only barrier between it and general surgery, and the effect is to belittle true orthopædic surgery and to emphasize the impression, only too pronounced that the tendency of the orthopædic surgeons of to-day is to make orthopædy a stepping stone to general surgery. The effect of this on legitimate orthopædic surgery can be imagined. If it should so happen that the present views of some of those who are known as orthopædic surgeons should prevail, there will be no orthopædic surgery, except as it may exist as an adjunct to general surgical practice, and the real foundation of orthopædy—that is, the study of mechanico-therapy—will be relegated to the instrument makers from whom legitimate orthopædic surgery rescued it not many years ago.

Your institution stands as the exponent of legitimate orthopædic practice. Until recently it has been hampered, by the lack of proper facilities, in the full performance of its work. During this time it has striven patiently and persistently to develop the much-neglected side of deformity surgery—namely, the unattractive mechanical side. But unattractive as is this part of the work to the average orthopædic or general surgeon, it is the important side, and it is the side of the work upon which the success of the treatment of a case of deformity depends. It seems almost useless for me to say that the same attention will be given to this part of the work in your institution in the future as long as I have the honor of being its surgeon-in-chief, and I dare to hope that my successor, whoever he may be, will hold the same views. The addition of an operating room simply enables us to treat our patients from both an operative and mechanical standpoint. It does not mean that the operative side will be developed at the expense of the mechanical work. It does not mean that there is any danger of your hospital being known as a general hospital, where all, or even many, of the operations of surgery are to be performed. If it becomes necessary for us to operate to overcome a deformity, and the patient requires special orthopædic care after operation, we propose to operate, but all other patients requiring surgical care will be referred to some general hospital, where they belong.

The future of orthopædic surgery depends upon the

deliberate study and development of the mechanical aspect of the work. There will always be operative surgeons who can perform the cutting operations which are sometimes necessary to relieve chronic deformity. On the other hand, there is to-day a scarcity of surgeons who understand, or who have been taught to apply, the principles underlying the mechanical correction of deformity. The student of mechanico-therapy needs encouragement, and the medical profession should understand more fully that it is only by a conscientious and prolonged study of both the operative and mechanical work that a fully equipped orthopædic surgeon can be produced. It is taken for granted even in our best medical colleges that a student is a natural mechanician—born to devise and apply apparatus in the treatment of chronic deformity—and yet I venture to say that there is no more delicate or difficult problem in the whole field of surgery.

Who will be the first one to endow a chair of mechanico-therapy, associated with a clinical professorship of orthopædic surgery, in one of our medical schools?

To apply an apparatus, already made, to a patient, to give a description of Smith's hip splint, or Jones's spinal brace, or Robinson's clubfoot shoe, or to apply a plaster-of-Paris splint in presence of a class of students, is like giving a simple verbal description of the quadriceps extensor femoris muscle to one who has never dissected a human body. Actual training in mechanical work is as necessary to a successful student of orthopædy as is dissection to an anatomist, or as clinical study and laboratory work are to the successful development of the well-trained medical man. As the old style of giving didactic lectures in medical schools has given way to more practical and scientific methods of instruction, so, in the future, the present methods of teaching orthopædic surgery will be re-enforced by practical work in the mechanical room. The perfunctory application of an apparatus before a class will give way to a description of the fundamental principles underlying the mechanical, anatomical, and surgical problems involved. The student will then be obliged to apply these principles under the instruction of the professor—and the student will thus gain a real knowledge of the subject.

When one sees, in the various instrument makers' shops, the many crude and incorrectly constructed instruments for the treatment of chronic deformity which are, literally, like sugar or salt, in the market, one can realize the embarrassment of the average medical man in his effort to cope with the treatment of a patient with a chronic or progressive deformity. His guide is the profusely illustrated catalogue of some enterprising instrument maker. His knowledge—for there are no textbooks on the mechanico-therapy of orthopædic surgery—is limited and his failures are many. The existing works on orthopædic surgery do not satisfactorily cover

this field. Whose is the fault? It lies wholly with those who teach, and it will be thus until the subject of mechanico-therapy, as applied to the problems involved in orthopædic surgery, is made an obligatory course in the medical colleges.

So far as is possible this work has been done in your institution in the annual course of lectures which have been given under your auspices for the past twenty years. It has been further amplified by throwing open the doors of the institution to those who wish to study the mechanical principles involved in the treatment of deformity, and many have availed themselves of this privilege. There are at present three or four surgeons from various distant cities who are following the work of the dispensary and hospital. Our work in this direction might easily be increased if it were more generally known that we always welcome those who wish to study our work and methods.

From causes entirely beyond our control the Morgan operating room was not completed until early in the summer. We had used the room only once when orders came to remove all the hospital inmates to the country, in anticipation of the extensive changes in the building—which have since been made. On this account, and also on account of the flying mortar dust arising from the demolition of the old building, it was deemed best to keep the operating room closed all summer. The furniture, etc., which was removed, has been replaced and the room is now in order and operative work has already begun.

It is due to the generosity of one of our trustees that we have a complete Röntgen-ray apparatus as a part of our regular dispensary and hospital work. Its use opens a large field for scientific work and study. It will serve to throw much light on that which has hitherto been obscure and difficult. In all the diseases and deformities of the major articulations and long bones, and also in other respects, its assistance in forming a picture of the conditions will be invaluable—and the entire medical staff desire to thank the gentleman who made this valuable present to the institution. It is with your approval that I announce to the medical profession that at certain hours and under certain conditions the X-ray apparatus will be placed at their disposal. [The remainder of the address was devoted to a statistical statement of the work of the institution during the past year.]

**A Conference on Leprosy.**—There will be held in Berlin in October, 1897, a conference of a very limited number of renowned leprologists and delegates of the different governments to discuss the slow but sure increase of leprosy and the measures to oppose to this plague. The conference was fixed for the month of March, 1897, but the scientific expedition of Professor Robert Koch to South Africa (for the British government) has made a delay of the date necessary. The members of the organizing committee are Dr. Armauer Hansen, of Bergen, Norway; Dr. Robert Koch and Dr. O. Lassar, of Berlin; and Dr. Edward Ehlers, of Copenhagen (secretary).

## Original Communications.

# INTRAVENOUS TRANSFUSION OF SALINE SOLUTION WITH A NEW APPARATUS.

By ELY VAN DE WARKER, M. D.,  
SYRACUSE, N. Y.

THE intravenous transfusion of saline solutions is such a simple operation that ordinarily no special apparatus is necessary. Every surgeon knows, however, that it is sometimes these very simple procedures that are difficult. In a case of extreme collapse, when the veins have no existence, physiologically speaking, and exist only anatomically as collapsed tubes, without radial pulse—when no amount of cording will cause the empty vein to fill, and when a lost minute may be measured by a lost life—it is very convenient to have a simple apparatus at hand that will expedite even so simple an operation. In these extreme cases I believe it is necessary to transfuse into the veins; subcutaneous transfusion is too slow with the vital forces so nearly suspended. Saline rectal enemas, a method of great value, for the same reason is too slow to furnish the necessary stimulus to a heart nearly inert for the need of a fluid to act upon. The apparatus here figured is a composite affair that was gradually put together from time to time as the need of transfusion occurred, until it reached its present perfected form.

While nearly every surgeon has had occasion to test the merits of saline transfusion, I doubt if any one has had the satisfaction of demonstrating its value as a lifesaver more thoroughly than I have had. With the object of inducing some one who has never tried it to be prepared to use it with a strong reliance upon its certainty of action, I will narrate briefly the following cases:

CASE I.—Miss M., of Irish nativity, aged forty-three years, large ovarian cyst of several years' duration, had suffered no unpleasant symptoms other than those due to abdominal distention. While nursing a sick relative, which caused very unusual exertion, she was suddenly attacked with severe abdominal pain and tenderness, with chills and subsequent fever. I saw her at the home of her relative about one week after the outbreak. The abdomen was of a dimension equal to a pregnancy at term, very tender on palpation, with frequent attacks of pain. Temperature, 103°; pulse, 110. I advised immediate operation, but it was nearly a month after my visit that she was admitted to the Central New York Hospital for Women for operation. During that interval the symptoms had gradually augmented, and at the time of her admission she was in a deplorable condition. She was greatly emaciated and too weak to walk. Section showed a monocyst almost universally adherent. The contents of the cyst were about twenty pounds of extremely fetid pus. The adhesions were easily broken down, and the operation in particular difficult, lasting about forty minutes to the completion of the toilet.

She was taken off the table in fair condition. It was soon noticed by the nurse that she was growing cold and the pulse racing, and in a few minutes she appeared to be in a dying condition—pulseless, gasping respiration of the dying, with complete surface anaesthesia. Intravenous transfusion of a one-per-cent. salt solution at 105° was at once made, using about twenty ounces of fluid. In this case it was very difficult to find and enter a vein, so complete was the collapse of the vessel. My trocar and cannula greatly expedited the operation. The result of transfusion was prompt and lasting and the patient's life was saved. The operation was very nearly bloodless, the adhesions showing no disposition to bleed as they were broken up. The conditions leading to collapse in this case were interesting, as demonstrating that it is not blood loss previous to, during, or subsequent to operation, but that any condition equivalent to blood loss will precipitate the moment of collapse. Here high temperature, arrested nutrition, and blood poisoning were those equivalent conditions.

CASE II.—A woman, aged thirty years, married, demiblonde, number of children unknown. In the service of one of the staff of the Woman's and Children's Hospital of Syracuse. Abdominal section reached a right pelvic hæmatoma due to what was supposed to be an extra-uterine pregnancy. An old clot was turned out of the pelvis equivalent to about a pound in weight. It was dense and tarlike in color, and at the time the lesion occurred, must have represented a quart, or possibly more, of blood. The phlegmon developed about six weeks previous to the operation, but its history was obscure. The loss of blood due to the operation was small. The patient was upon the table about forty minutes. After being put to bed in a fair condition of pulse, she surprised us by passing quickly into extreme collapse. She was aligid, with complete surface anaesthesia, eye and other reflexes abolished, pulseless, and the veins completely collapsed. The respiration was gasping and shallow. At the request of the operator I performed transfusion. I was about to abandon the operation on account of the impending death, but as she was yet gasping and the trocar nearly in the vein, I persevered, and in less than a minute the solution was being transfused. The effect was rapid, and the patient passed from a condition of inevitable death to one of comparative safety in about three hours. She made an uneventful recovery.

CASE III.—As anæmic shock is not the only form with which the surgeon has to contend, it is well to refer briefly to the following case with a view to contrast:

Miss —, aged twenty-one years, single, had always been a delicate girl. At seventeen years she had not yet menstruated. Her physician detected a pelvic mass extending like a ridge from side to side. As she was bedfast and rapidly failing, laparotomy was advised and consented to. She was admitted into the Woman's and Children's Hospital of Syracuse. The mass was made up of the lower border of the omentum fusing into the right tube and ovary, all of which were removed. She made a prompt recovery, and improved very considerably in general health. The pelvic condition was regarded as tubercular, although I am not sure that it was verified by the microscope. Four years after she was readmitted with symptoms of intestinal obstruction. At the request of her physician, a colleague on the staff, I did the operation. The intestines, large and small, were greatly distended. At first it was supposed that the obstruction was at the sigmoid, but

in the Trendelenburg position it was seen that what appeared to be a constricted part of the colon was a cyst of tubal origin which was tied off. At this point a serious accident occurred. The intestines, which had been retained in the abdominal cavity only by great care and watchfulness, through the momentary inattention of the assistant were allowed to escape. As usual in such a case, the intestines were reduced with extreme difficulty and loss of time. They were at last returned and the search for the obstruction resumed. It was found not far from the ileo-cæcal region, and consisted of a globular mass surrounding and obliterating the intestine. It was found necessary to resect the intestine at a healthy portion and insert a Murphy button. The operation lasted about an hour. She was put to bed in fair condition; pulse about 120; respiration, 18; temperature, 99.5°. This was at 3 P. M. While at dinner in the evening I was called to the hospital by my colleague in consultation in the case. I saw her at 7 P. M. Temperature, 104°; respiration, 30; pulse racing. At 8.30 P. M., pulseless at the wrist; temperature, 104.6°; respiration, Cheyne-Stokes. At the request of my colleague I made transfusion in the hope that an increased volume of fluid would stimulate the fast failing heart. Owing to the carelessness of a nurse the amount transfused is not known. It had no effect upon the circulation. She died at 10 P. M. with a temperature of 106°.

The case is given somewhat in detail as it demonstrates in a striking manner the limits of saline-solution transfusion. The three cases serve to define three forms of shock. First, we find shock due to inanition, fever, and chronic sepsis, precipitated by operation. Second, shock due to blood loss prior to operation, and both forms to amend to transfusion. In the third, the fatal condition, or shock, comes from suspension of inhibitory nerve centres that functionally control the heart and heat centres. The train of conditions that led up to this is clear when we recall the eventration, and all that it implied to the nervous system. The entire nervous congregation of organic life was roused into fatal overstimulation through the irritation of the greater and lesser splanchnic nerves, and the brain and spinal centres implicated through the great sympathetic, quickly resulting in suspension of inhibitory centres. Thus, while saline transfusion was able to supply the deficiency in loss of circulating fluid, it was unable to supply what was necessary in the other. Clinically the two types stand in marked contrast: In the first, advancing algidity; in the second, augmenting pyrexia. In the first, surface anaesthesia increases as surface heat is lost; in the second, only as the brain ceases to functionate. In the first, consciousness is lost in the same ratio as the pulse is lost and the heart's action fails; in the second, rather with the increasing pyrexia. In the first, torpor from the beginning, intensifying cold, death. In the second, restlessness, intensifying heat, death. One is as much deserving the name of shock as the other, and we have no other name for either. As intravenous transfusion has now a status as a life-saving operation beyond all controversy, it is well to be able

to define just in which type of shock we may expect these results, and as a contribution to this knowledge I have ventured to overstep the limits of the paper and introduce the third case.

In several instances in which the apparatus has been exhibited before societies, several gentlemen suggested that just as prompt results could be gained from rectal or subcutaneous injection. I have no doubt that is so in cases in which function is not too seriously depressed. But in cases in which death is near and time a serious matter, I would not advise any to trust to it. I have had some experience that has practically taught me this lesson. I have found rectal hot saline injections of great value in supplementing intravenous transfusion when the radial pulse is re-established and the reaction appears to drag; then the injection appears to augment the effect of the transfusion. When reaction is established to this degree, the rectum in my experience offers as favorable a channel as the subcutaneous route, and leaves no painful sequelæ.

The physiological study of intravenous injections has begun to awaken keen interest. MM. Bosc and Vedel, in the *Journal des praticiens*, July, 1896, have reached the following conclusions from their study of the subject: Large intravenous transfusions are not toxic even when transfused as rapidly as forty to eighty cubic centimetres a minute. These injections produce an abundant diuresis in half an hour after the transfusion. While this is, no doubt, true in physiological experiments, I have not observed it in cases of extreme collapse in the human subject. There is no elevation of blood pressure and no albuminuria, but there is increased heart action and an elevation of the central and peripheral temperature—febrile reaction. They quote Mayet that in the compound saline solution—chloride and sulphate of sodium—the sulphate is of no value and should be avoided, as it affects the blood globules, although the authors say there is no difference between the effects of the two solutions. Fasting animals appear to be more susceptible to large injections, but even when apparent death results the animals quickly recover. In these experiments it was shown that the physiological effects were not in proportion to the temperature of the solution and the rapidity with which the injection was made. The authors recommend a simple saline solution, one hundred and five grains of sodium chloride to thirty ounces of water to be the preferable proportion. In the hasty approximation of the operating room, a teaspoonful to a quart of water is a good working formula.

In the employment of the intravenous injections after the hæmorrhage of typhoid fever—and it ought always to be used when collapse threatens—it has recently been shown that the beneficial effect is not confined to merely increasing the volume of the circulating blood. There is a far-reaching and profound effect that can not be measured in this mechanical way. M.

Claissé, in the *Comptes rendus de la Société de biologie*, 1896, has made his study upon the blood from the fact that in many infectious diseases increased leucocytosis is a constant attendant. "In a case generalized purulent streptococcus infection an intravenous injection of fifteen hundred grammes of saline solution was followed in an hour and a half by a rise of temperature from 102.9° to 105.8°, while the number of red blood-globules to the cubic millimetre was reduced from 3,968,000 to 3,596,000, and the number of white blood-corpuscles from 13,547 to 7,804. In the course of three hours the temperature had declined to 98.6°. In the case of an old man of sixty-four years with a diffuse phlegmon of the arm, a subcutaneous injection of a litre of saline solution was followed by a diminution in the number of red blood-corpuscles from 3,565,000 to 3,255,000, and of the colorless corpuscles from 26,660 to 11,346. In a case of profound puerperal infection an intravenous injection was immediately followed by an alteration in the relation between the red and colorless blood-corpuscles—1 to 228 to 1 to 344." In the comment of the *Medical Record*, from which this extract is taken, it is pointed out that the depression of temperature, diminished leucocytes, and amendment of the symptoms of infection with a status of reaction are similar to those following the injection of antitoxine in diphtheria. "A splendid field for research is thus opened up, and one that possibly will render the animal serums useless in the treatment of specific infections." I am strongly of the opinion that in view of the enormous renal stimulation following intravenous injections of saline solutions, and the marked kidney implication in diphtheria, together with the profound effect of the injection upon the corpuscular elements of the blood, this will prove an accepted treatment of diphtheria in the near future. In typhoid fever, in view of this report by Claissé, the saline transfusion has a double indication in hæmorrhagic cases. In puerperal infection I shall certainly try it. In cases of the nearly functionless kidneys of eclampsia and with the poison-laden blood it is positively indicated, and, I believe, has already been tried, but I have lost the reference.

From this brief abstract of what has already been accomplished in the therapeutics of saline solutions transfused directly or indirectly into the blood, it is evident that its usefulness in the future may be broadened far beyond the expectations of those who have heretofore limited its use to the treatment of shock or hæmorrhage. In fact, to the physician, rather than to the surgeon, will we look for this more important demonstration of its utility. Simple as the operation of intravenous transfusion may be, yet an apparatus that renders it easy to perform, aseptic and accurate in operation, will contribute an important element to this more extended employment of the method. To the physician who is but seldom called upon to make any surgical operation, the little apparatus here figured will prove of great usefulness.

The apparatus consists, first, of a glass container large enough to hold from three pints to two quarts of solution (Fig. 1), fitted with a sufficient length of pure gum tubing given off from the bottom of the container. In the figure the tubing is represented as con-

FIG. 1.

nected with the stopcock C, Fig. 2, with the cannula D, Fig. 2 attached, and in the condition in which it is when in use, the cannula inserted in the vein and the stopcock open. The glass has a scale of ounces etched into its side, so that the quantity of fluid transfused at any stage of the operation may be readily ascertained. The second part of the apparatus (Fig. 2) consists of a cannula D, the trocar B, and the stopcock C. One

FIG. 2.

end of the cock is corrugated so as to be firmly held by the distal end of the tubing. The other end of the cock, as seen in the figure, is slightly tapered so as to slip into the head of the cannula, which is beveled to correspond, so that when connected with the cannula an airtight taper joint is formed. The trocar B has a head sufficiently large to be easily grasped by the fingers and withdrawn when the cannula is inserted into the vein.

The operation is done by the use of this apparatus as follows: After the vein is exposed, the only instrument not here figured is a small mouse-tooth forceps to pick up the vessel, which is quite necessary; but any small forceps will serve the purpose. The container has been filled and the stopcock connected with the tubing is held by an assistant. The cannula and trocar together are inserted into the vein, which is held up by the forceps, so as to offer a slight shoulder to the sharp point of the trocar which is thrust into the lumen

of the vein, being careful not to transfix. The stopcock is now opened, and the solution allowed to escape until the tubing is thoroughly warmed and the solution discharges at a proper temperature. You are now ready to withdraw the trocar and thus open the cannula, through which the blood flows more or less freely. The stopcock, still open and the solution discharging, is at once connected with the cannula by the taper joint—simply thrusting the two together. It is thus seen that the two currents, one of blood from the cannula and the other of saline solution through the cock, are joined without the possibility of the entrance of air. The flow of solution is regulated by the cock as well as by the height at which the container is held above the point of delivery. In the case of collapsed veins after a very exhausting hemorrhage or extreme shock, no blood will escape from the cannula after the trocar is withdrawn. Fig. 2 represents that part of the instrument somewhat shorter than the actual length and about half the diameter.

#### A CASE OF

### INOPERABLE SARCOMA OF THE NECK

TREATED BY INJECTION OF  
THE MIXED TOXINES OF STREPTOCOCCUS ERYSIPELATUS  
AND BACILLUS PRODIGIOSUS.

By HENRY L. SHIVELY, M.D.,

PHYSICIAN TO THE PRESBYTERIAN HOSPITAL DISPENSARY.

THE publication in the *American Journal of the Medical Sciences* for May, 1893, of a paper by Dr. W. B. Coley, entitled *The Treatment of Malignant Tumors by Repeated Inoculations of Erysipelas, with a Report of Ten Original Cases*, aroused the hope that an important step had been taken toward a successful plan of treatment for inoperable cases of carcinoma and sarcoma. Whoever has watched the progress of malignant disease after repeated operations, each successive operation more extensive and more mutilating and only to be followed by inevitable recurrence, must have felt in duty bound to make a trial of any method which promised better results. The further work of Dr. Coley was followed with interest, and, with the reports of additional cases and improved methods of using the erysipelas toxines, together with corroboration of his results in the experience of other observers, the new treatment seemed to have secured a fair claim to recognition and further trial. The adverse report, however, of the committee of the New York Surgical Society (*Annals of Surgery*, July, 1896), and the recent address in surgery before the American Medical Association by Dr. Nicholas Senn, in which the distinguished surgeon declared "the treatment of inoperable sarcoma by injection of the sterilized toxines of the streptococcus of erysipelas and the *Bacillus prodigiosus* had not accomplished the results expected," will certainly discourage

the rank and file of the profession from further trial in this direction.

The publication of the following case, which was first seen by the writer on March 7, 1895, may therefore not be untimely:

William F. S., aged thirty-five years, a butcher by occupation, has been a moderate drinker for ten years. He denies venereal disease, and there is no morbid family or personal history. He was in his usual health until the middle of December, 1894, when he observed for the first time a swelling of the neck on the right side below the ear. He thinks he may have hurt his neck in carrying heavy sides of beef on his shoulder. The lump became tender and painful, gradually increased in size, and the pain grew more severe, radiating over the entire corresponding side of the head. The patient began to lose flesh and strength, his appetite failed, and he could not sleep on account of the pain. Treatment gave him only temporary relief. For four weeks he has had difficulty in taking solid food, the dysphagia has increased, and for the past three days deglutition of liquids even has been embarrassed. In the past week his voice has become altered, phonation is thick and oppressed, and he expectorates a large quantity of thin, blood-stained, frothy mucus. He took to his bed February 20th. On physical examination the patient is poorly nourished and anæmic. The heart and lungs appear normal. Behind the angle of the right jaw there presents in the tissues of the neck a rounded tumor four inches long and three wide, the long axis corresponding to that of the neck. The tumor is immovable and firm in consistence, tender on palpation; the overlying skin tense, but not adherent. The region of the right tonsil and adjacent soft palate and pharynx are occupied by a smooth, bulging mass over which the mucous membrane is injected and hyperæmic. The right nostril is partially occluded and discharges a glairy, blood-stained secretion. The right pupil is smaller than the left. The glands of the neck do not appear to be enlarged, but the entire right side of the face is slightly swollen.

A clinical diagnosis of sarcoma was made, and, as the situation and extensive involvement of neighboring parts clearly precluded the possibility of successful operation, the patient was placed on tonic and symptomatic treatment. As was expected, the tumor continued to increase in size, the rapid encroachment upon the pharynx resulted in ever-increasing difficulty in swallowing, and the patient appeared to be rapidly failing from inanition and cachexia. The case seemed to be a promising one for the toxine treatment, and Dr. W. B. Coley was called in consultation. A "core" section of the growth was removed under cocaine and was examined in the pathological laboratory of the Cancer Hospital. The microscope showed it to be a typical small round-celled sarcoma, and as such was considered especially favorable for the treatment proposed. A supply of the mixed toxines, sterilized and unfiltered, of erysipelas and *Bacillus prodigiosus* was obtained, and on April 8th, at 5 p.m., the patient was given his first injection of half a minim in the substance of the tumor. About an hour after the injection he experienced a slight chilly sensation, but no distinct rigor, and at seven o'clock his temperature was 101° F.

April 9th.—At 3.15 p.m. an injection of three quarters of a minim was given with the usual antiseptic

precautions. At 3.55 the patient had a severe chill which lasted for ten minutes. At 4.30 p. m. the temperature was 99.5° F., and in fifteen minutes rose to 101.5°. There was some uneasiness of the stomach, but otherwise the patient was doing well, and after staying with him for half an hour I went away. At 5.45 I was sent for in haste as the patient was said to be "choking." Upon my arrival I found that on sitting up to expectorate he had suddenly become faint and had fallen back unconscious. He had rallied somewhat, but was soon seized with a facial spasm, the corners of the mouth twitched, his eyes turned up until scarcely more than their whites were visible, he relapsed into unconsciousness, and stopped breathing. His face was livid, and, as there was no indication of a spontaneous return of breathing, artificial respiration was begun. The pulse throughout was fairly good, somewhat weak, but at no time exceeded 120. The surface of his body was cold and bathed in a profuse clammy perspiration. The pupils were insensitive to light, there was decided trismus, and at times general muscular rigidity. There was absolutely no respiratory movement, and when artificial respiration was suspended the patient would relapse and cease to breathe. He was freely stimulated with whisky and hot water *per rectum*, and hypodermic injections of aromatic spirits of ammonia, whisky, and one twenty-fifth of a grain of nitrate of strychnine. Warmth was applied by means of hot blankets and water bottles. Under this treatment he would partially revive and breathe better, but several times he relapsed and had every appearance of being in *extremis*. It was nearly four hours before he was fully restored and out of danger. Temperature during this period was normal in the axilla.

10th.—The patient is somewhat prostrated, but otherwise shows no bad effects from the untoward symptoms of yesterday. Temperature normal. Injections are deferred for the present.

11th.—Patient feels quite bright and comfortable to-day. He thinks that he can swallow better than for some time past. The skin appears to be less tense over the tumor and his wife fancies that she can see some diminution in its size.

12th.—There certainly has been an amelioration of the symptoms; the tumor is perceptibly smaller and the patient is free from pain. He has been receiving two drachms of a solution of morphine, a grain to the ounce, every four hours. This is discontinued. The patient and his friends feel much encouraged in spite of the alarming symptoms following the second injection, and desire to have the toxines continued. As a forlorn hope and with some misgivings the treatment is renewed, and at 7.30 p. m. he was given another injection of a third of a minim, which was followed in half an hour by a severe chill which lasted for twenty-five minutes. At 10 p. m. he was fairly comfortable and temperature was normal.

13th.—Patient's condition is much improved, his voice is much clearer, pain has entirely disappeared from head and neck. The right side of the face is no longer swollen and the edema of the right eyelids has subsided. The pupils are no longer unequal. For the first time in two weeks the patient has swallowed solid food. The tumor measures to-day but two inches and three quarters in its long axis by two inches in its transverse diameter.

14th.—On account of indiscretion in eating too much yesterday patient's stomach is irritable, and for this reason injection is omitted.

15th.—Patient swallows without any difficulty; ate a pigeon to-day, and sat up for three quarters of an hour. He slept well all last night. His color is much improved and his voice is quite natural. The remarkable diminution in the tumor continues; its superficial measurements are two inches and a half by an inch and three quarters. The patient is very cheerful, and the entire aspect of the case seems changed. A third of a minim was injected at 7.30 p. m., followed by the usual chill and elevation of temperature.

16th.—Patient sat up for an hour to-day and he continues to do well. It is difficult to restrain his craving for solid food, which his stomach is too weak to bear well. A stomachic tonic is prescribed.

17th.—One third of a minim is injected to-day, followed by the customary reaction. Patient is improving in nutrition and strength.

20th.—The tumor appears to be about stationary in spite of daily injections of one third of a minim. To-day there was no reaction following administration of the toxines.

21st.—There appears to be a considerable increase in the size of the growth, and it is determined to increase the amount of the injection. After half a minim there was a slight chilly sensation.

22d.—The tumor has rapidly grown larger and is now only about a third less than its size when treatment was begun. A dose slightly more than half a minim is followed by but little reaction.

23d.—Patient can not swallow so well, and begins to look cachectic again. In spite of daily injections the tumor does not decrease, but rather grows larger.

24th.—Nearly a minim was injected to-day and was followed by a chill.

25th.—A good chill and sharp reaction followed the administration of a full minim to-day.

26th.—After one minim patient had elevation of temperature but no chill.

27th.—The tumor now measures five by four inches—a decided increase over its size at the time of beginning treatment. Swallowing is again very difficult, and patient's general condition is poor. No chill followed the injection of one minim and a quarter to-day. It is now apparent that no reduction in the size of the tumor is to be expected when no reaction follows the injection of the toxines.

28th.—A hard chill followed three quarters of an hour after the injection of a minim and a half to-day.

30th.—The amount of the injection was increased to one minim and three quarters and was followed by a chill.

May 1st.—Some improvement is to be observed again in the size of the tumor. It has decreased to four inches by three and a half. The reduction seems to be proportionate to the severity of the reaction following the exhibition of the toxines. Two minims are injected to-day, but there is no chill.

2d.—No injection.

3d.—Patient received two minims and a quarter and had a hard chill which lasted three quarters of an hour.

4th.—There has been a rapid decrease in the size of the growth, and the patient can again swallow solids without difficulty; has taken chops and eggs to-day. There was no reaction after an injection of two minims and a quarter.

5th.—Two minims and a half injected; no chill.

6th.—The injection was increased to three minims, and a sharp chill followed fifteen minutes later.

7th.—Three minims are injected. There is a marked improvement in all the symptoms and a further decrease in the dimensions of the tumor.

8th.—Three minims and three quarters are injected; no chill.

9th.—Four minims are followed by no reaction.

10th.—Five minims are injected, followed by a sharp chill, nausea, and vomiting, and great prostration.

11th.—Tumor is reduced to three inches by two and a half inches. On account of the severe reaction following the injection of yesterday none is given to-day.

12th.—The tolerance for the toxins has increased to a point where five minims produce no reaction.

13th.—Five minims and a half are injected; no chill.

14th.—After six minims to-day there was a hard chill and fever.

15th.—An appreciable diminution in the size of the tumor can be seen since yesterday. Injection of six minims and a half is followed by a pronounced chill.

16th.—Dose is increased to six minims and three quarters and there is a good reaction.

17th.—Patient was up and about the room all day and he is entirely free from pain. Seven minims and a quarter are injected.

20th.—The injection has been gradually increased up to nine minims and a quarter, after which there was a hard chill and considerable nausea.

21st.—There has been a continuous and rapid diminution in the size of the tumor, which is now movable and painless. Nine minims and a half were injected without reaction. Patient is up and about and walks out every pleasant day.

22d.—Injection of ten minims was not followed by a chill, but there was much vomiting, which has weakened the patient.

23d.—The injection is omitted.

24th.—Eleven minims injected; no reaction.

25th.—Eleven minims and a half; no chill.

26th.—Injection of twelve minims was followed by a hard chill and vomiting.

27th.—Injection is omitted, as patient is despondent and stomach is unsettled.

28th.—The tumor is scarcely visible; on palpation its measurements are an inch and three quarters by an inch and a half. Stomach is much better, and nourishment is well borne. Twelve minims were injected to-day and fifteen minutes later the pupils dilated and there was a slight clonic convulsion of the arms and face, but no loss of consciousness. The area of the tumor about injection became hot, red, and swollen. A hard chill and fever followed.

29th.—No injection.

30th.—Eleven minims are injected; no reaction.

June 8th.—For the past week the patient has not done so well. A small, superficial abscess formed over the site of the injection of May 28th, which is opened and dressed. As tolerance of the injections is acquired there is a cessation of improvement. If the injections are discontinued a few days there is an increase in the tumor as rapid as is the improvement when the injections are given. Certainly, in this case, experience does not justify the hope of a permanent cure, and the systematic use of the injections is abandoned. For the following month they were used merely as a palliative to relieve pressure symptoms. The patient gradually failed, and died of exhaustion on July 9th.

It is believed that an impartial survey of the facts here recorded can not but convince one that there was an immediate and pronounced influence of the toxins in causing retrogression and absorption of the tumor mass, and, although a cure was not effected, yet the patient's urgent and distressing symptoms were relieved, he gained for a time in flesh and strength, and his life was probably prolonged. When the pitiable hopelessness of his condition is considered, then, the results of treatment can not be deemed an entire failure. It is also apparent from the symptoms following the second injection that the toxins may act as a powerful poison, having a direct paralyzing effect upon the respiratory centre. Notwithstanding, however, its possible dangers and the uncertainty of its action, the toxine treatment constitutes at present our only therapeutic resource for inoperable malignant disease having well-authenticated cases of recovery to its credit. Should not the patient have the benefit of its trial?

145 WEST SIXTY-SIXTH STREET.

## CORSICAN FEVER.

By W. W. SKINNER, M.D.,  
FORMERLY OF AJACIO, CORSICA.

DURING certain months of the year those who reside or travel in Corsica are in danger of having what is commonly called Corsican fever. These are the summer months, from the middle of May to the time of the autumn rains, which usually occur in October. This danger is especially great for foreigners and the unacclimated, but native Corsicans are not entirely exempt, although the attacks of the malady that the latter experience are usually milder in intensity and rarer in occurrence than those to which the foreigner is exposed. There is no warning of the imminence of an attack, no apparent reason for apprehending danger to a visitor to this beautiful island who, choosing the late spring or the summer for his visit here, does not perceive why he should not profit by the delightful climate and the clear atmosphere in the midst of which he finds himself, to see the various points of interest offered for his enjoyment. Only the knowledge derived from the previous experience of others is there to prove to him the existence of this invisible enemy. It is, however, chiefly the coast and the lowlands that constitute the regions of danger; the high mountains in the interior are, on the contrary, regions of safety and salubrity.

The term "Corsican fever" is not, of course, an accurate nosological expression. A disease can not be scientifically named after the locality in which it is observed any more than it can bear the name of the man who first or best described it. There are, nevertheless, many regions after which fevers have been named. Thus we hear of Roman fever, African fever, coast

fever, Indian fever, valley fever, etc., in all of which the pathogenic element is probably one and the same.

The fever which forms the subject of this article is acquired by simply living in the infected region, and by not taking sufficient and minute precautions against it. If a visitor to Corsica were to live during the summer in Bastia, Ajaccio, or Aleria as he would if he were in New York, Philadelphia, or Boston, he would undoubtedly present a fine case of Corsican fever before the summer was over. The sightseer who walks or drives about the country or the towns, the day laborer at work in fields or factory, the sportsman in quest of game, the housewife at her duties, are alike subject to this affection. It is an infectious disease and the germ is breathed into the system with the air, perhaps also taken into the stomach with food or drinking water. One ætiological factor, however, is predominant, and that is exposure to cold or wet. One patient under the writer's care, who was in the habit of always wearing a hat or other head covering when out of doors, took advantage of the mild temperature one beautiful spring evening to take a short walk bareheaded after sundown. Within forty-eight hours she had "the fever." Another took a drive one sunny afternoon, but the light breeze, increased by the speed of the carriage, caused a slight feeling of chilliness during the drive. Result, confinement to bed for a few days with "the fever." It is a common experience for a sportsman or a workman caught in a shower and drenched to have an attack of fever afterward.

Age has little or no causal influence, nor has sex. A girl baby eight months old, still nursing, came under the author's observation that presented a typical attack of this affection, in which the temperature reached the respectable figure of  $41.2^{\circ}$  C. ( $106^{\circ}$  F.), but was promptly amenable to the usual treatment. From this age to that of advanced life in both sexes it is common to find cases of fever in spite of the numerous and incessant precautions taken against it.

There is one curious feature about this fever in connection with altitude which is worth mentioning. Several cases have been observed in which the subjects experienced no rise of temperature and no pathological symptoms so long as they remained in regions of about the same level, notwithstanding that these regions were unsanitary and that the fever was prevalent there. But as soon as these persons left the lowlands and abruptly ascended to a mountainous region of three to four thousand feet, they would begin to have attacks of fever in a day or two after their arrival in the mountains, where fever is never acquired. It would seem as if the organism of the patient made an effective resistance to the disease as long as it was in the unhealthful environment, but that the moment the organism realized that it was no longer living in the midst of germs it would relax its vigilance, or, in other terms, abandon its resistance to the disease, thus giving the latent malady an oppor-

tunity of manifesting itself. In the words of the patients, the altitude and the corresponding lower atmospheric temperature and pressure seem to "bring out the fever."

There are certain hours of the day which experience shows to be more favorable to acquiring the fever than others. These are the hours when dew is falling or about to fall, or again when it is redissolving and evaporating. The hours about sunrise or sunset are particularly dangerous. The natives of this island are well aware of this fact and regulate their hours of agricultural labor accordingly. An interesting example of this kind is to be observed on the east side of Corsica, where the sea is bordered by a long, low, level stretch of coast extending several kilometres inland. There the land rises and soon becomes mountainous, thus insuring immunity from the fever. This lowland, however, is very fertile, although excessively febrigenous. So the owners and workers of this pestilential ground are obliged to live in the mountains and go to their work on horseback, because the distance is so great. In this way it is their habit to ride hastily down to their fields in the middle of the morning, work there during the few midday hours, then, as the sun sinks in the west, to mount their horses again and fly in all haste to the highlands, thus escaping an invisible foe.

Corsican fever presents itself in several forms. Commonly it occurs in a remittent form, the temperature of the body increasing to an abnormal degree during part of the day, then subsiding to the normal for a few hours. Not infrequently it is subcontinued or even continued, the daily remission hardly descending to normal or else not approaching within one degree of the normal. More rarely it is frankly intermittent, but even in these cases it is not often of a clear tertian type, still less a quartan, but rather of the unsatisfactory daily type.

The prodromata are such as usually mark the approach of a fever of paludal origin: diminution of appetite, lassitude, mental sluggishness, heaviness of the head, etc. In a day or two these symptoms increase, and there is added a sensation of chilliness creeping up and down the vertebral region and the lower extremities, or even a distinct chill. These sensations often occur in the late hours of the afternoon or in the evening, and last an hour or two.

The digestive tract offers its quota of symptoms. The tongue is more or less coated. Emesis is often observed in infants and young children, anorexia and thirst in the adult. A certain degree of emaciation obtains if the disease is not promptly treated, and the countenance betrays a state of suffering; the features are drawn, the complexion sallow or leaden. Not infrequently an unhealthful purple flush discolors the cheek, while frontal or general cephalalgia is the rule.

In regard to sudation during an attack of this fever there is a marked difference in individuals. Many will

retain a hot, dry skin throughout the entire day. Often there is a suspicion of moisture as the temperature is subsiding, while in other cases marked perspiration occurs, though usually it is not so profuse as in typical cases of malarial intermittent fever.

The spleen is not of necessity enlarged. In a large number of instances it is not perceptibly increased in volume, even when the intensity of the fever is great and the patient obliged to remain in bed continuously. In other cases it presents enlargement. Megalosplenitis is thus seen to be an inconstant sign notwithstanding the fact that a given case may be one of great severity.

Elevation of temperature is the most prominent and constant symptom, and often the only one upon which the physician can base his diagnosis. It begins in the morning and is sometimes unperceived by the patient until the earlier hours of the afternoon. It persists until sunset, and even until after the patient falls asleep for the night. Its intensity varies from a few tenths of a degree above the normal to  $41.5^{\circ}$  ( $106.5^{\circ}$  F.) and still higher. The victim is not always forced to take to his bed, but usually does so during the hours of highest fever, and especially as the disease advances, when he becomes weaker and less resistant. These characteristics of the temperature serve as an excellent means of diagnosis between Corsican fever and the various intermittent forms of pyrexia observed in hepatitis, tuberculosis, urethritis, etc.

The diagnosis is made chiefly by exclusion. If there is no pulmonary disease or affection of the digestive tract, including the liver, to account for the symptoms, the presumption is already in favor of Corsican fever. When, in addition to this, the peculiarities of the temperature are considered, and also the fact that the attack repeats itself daily in the same manner, or at least increases gradually in severity, all doubt is dispelled, especially if the specific mentioned under the head of treatment produces its desired therapeutical effect.

Various complications are capable of more or less completely masking the fundamental disease. Thus one patient had an acute cystitis in the course of an attack which soon drew to itself the greater part of the attention, both of the physician and the sufferer, on account of its severity. Frequent and painful micturition, vesical tenesmus, great pain upon exploration of the base of the bladder, and quantities of pus in the urine, were symptoms fully justifying the diagnosis of this complication. A change of air from the low region, where the attack began, to the mountains, twelve hundred metres above sea level, produced more benefit in this case than all other means combined, for it effected a complete cure both of the fever and of the cystitis.

Pleurodynia has also figured as a complication, as well as megalosplenitis without fever. It is not rare to observe the congestion of certain organs, as liver or lung, especially in the early stages of the infection be-

fore the disease has fairly decided, so to speak, to subside into its monotonous habitual form.

Curious to note are the forms without fever. Paradoxical as this may seem, it would be still more so if we did not already know of analogous cases such as those of typhoid fever without elevation of temperature. They are usually characterized by the predominance of some symptom not usually attributed to fevers of this nature. Thus the patient may complain simply of a neuralgia, a cephalalgia, a diarrhoea, or even a herpes zoster. One patient, otherwise in perfect health, was tortured by most excruciating pain due to neuralgia of the gluteal region, but only during certain hours of the night, from ten till twelve o'clock. Another had a circular area of herpes zoster that defied all treatment until the true nature of the cause was finally suspected and remedial measures applied accordingly. Still another presented a most incoercible diarrhoea that neither dieting, nor lying in bed, nor opiates, nor astringents would modify in the least. When at last the remedy for Corsican fever was given the diarrhoea ceased as if by magic.

The treatment of this disease requires but few agents, the principal among which is quinine. To speak of fever in this island is to suggest the use of quinine, and it is astonishing to perceive what enormous quantities are used and what Rasorian doses are sometimes taken. An old-timer does not bother himself to measure it by grains or grammes; he simply takes a teaspoonful, more or less, at a dose. It is evident, too, that in some way the taking of an ordinary dose by the mouth becomes ineffective after a time, so that those long accustomed to such doses do not feel the effects nor reap the benefits from them which they have a right to expect. Hence the almost unlimited increase in dose as the effect is found to be less. In such cases another manner of administering the remedy is advantageous, such as the hypodermic method or even the enema, in which a smaller quantity of quinine suffices.

Antipyrine given in conjunction with quinine often hastens and augments the antipyretic effect of the latter, but has in itself no specific action. Ergotine has also been lauded for the same reason, but my personal experience with it is limited and unconvincing. Cold douches, short and sharp, over the whole of the cutaneous surface are an excellent adjunct in fighting this disease. They often start a patient toward recovery when other measures fail. The surest and most radical way to cure the fever, however, is to leave the country.

It was noted above how the tillers of the soil descend from the healthful heights on horseback to attend to their crops in the lowlands in the middle of the day, and return again at night in order to avoid the fever. There is another custom among harvesters and hay-makers of sojourning a time in the mountains after the pressing work of caring for the crop is finished. These men, during the few days of hurry incident to

haymaking and harvesting, are obliged to pass the night near the fields in which they work, and if these are situated in the low valleys, as is chiefly the case, they are sure to be exposed to an attack of the fever. They work as rapidly as possible, therefore, to finish gathering the grain at the earliest moment; but as soon as this is done they betake themselves with all dispatch to the mountainous interior, where they pass several weeks throwing off the infection acquired in the lowlands. Thus during the month of September last year, there were upward of sixty harvesters at the town of Bocognano, situated in the interior of the island at an altitude of three thousand feet above the sea level, who had been working in the grain fields of the beautiful but pestiferous region of Campo del Oro near Ajaccio. They expected to escape the fever by this change of living, or to cut it short should it develop.

Perhaps one of the most important points for strangers visiting Corsica is how to avoid the fever; therefore a word on prophylaxis would not be out of place here. The safest time of the year to visit this beautiful island is between the months of November and April. Even then some precautions must be taken. One must avoid sudden changes of temperature, and not be unexpectedly found without sufficient clothing for perfect comfort. One must avoid being drenched with rain or becoming wet when out driving, fishing, or shooting. It is best to avoid currents of air. One old practitioner of Ajaccio invariably forbids a patient to have even his windows open during his illness. The time of sunset and the hour immediately following is an unsafe one in which to be out of doors to those unaccustomed to the climate. Many attacks can be traced to the imprudence of staying out "to watch the lovely sunset."

From the foregoing it will be readily seen that Corsican fever is but a form of malarial fever, or rather that it is one of the manifestations of that protean and widely disseminated pestilence called malaria. Its prevalence in low, marshy regions; the manner of its onset; its character of essential fever as distinguished from symptomatic fever; its partial, perverted, and vicarious forms as shown in the neuralgias, herpes, diarrheas, etc., of which the attack sometimes consists; and above all its amenability to the great antimalarial specific, quinine, all establish its relationship to malaria.

#### EXPERIMENTS UPON THE EFFECTS OF DIRECT ELECTRIZATION OF THE STOMACH.

By MAX EINHORN, M. D.

OF late direct electrization of the stomach has been frequently made use of with beneficial result in the treatment of chronic gastro-intestinal affections. Some writers even go so far as to place intragastric electriza-

tion at the head of the therapeutic means available in the treatment of the manifold dyspeptic conditions.

The explanation of how the current exercises its curative effect has a merely theoretical interest. In regard to the practical use and value of a certain remedy, it can be at present estimated by empirical results alone. This being obtained in numerous cases by various authors, and being favorable, the remedy will have to be pronounced useful, otherwise not.

The reports on intragastric electrization which have of late been published are quite numerous and very favorable. This mode of treatment is, therefore, of great value and deserves to be still more promulgated than it thus far has been.

That old, well-recognized remedies which have stood the test of experience are occasionally repudiated by physiological experiments is an occurrence which has been of late frequently observed. I need only mention, as an instance, the effect upon the stomach of the bitter remedies (*amara*), which has been refuted by the experiments of Tschelzoff on dogs and of Jaworski on human beings. Notwithstanding this, the "*amara*," continue to be used, and I should not be astonished if new experiments, arranged somewhat differently, should prove the efficacy of this class of remedies and obtain for them warm advocates.

\* Although I am, myself, an ardent believer in experimental investigation, I am, nevertheless, of the opinion that old facts should not be so quickly upset.

If we now again turn to direct electrization of the stomach, we find that an important investigator has recently written against this therapeutic means, basing his views entirely upon experiments made on animals. I mean Dr. S. J. Meltzer.\* Intragastric electrization being of practical importance and high value, I consider it opportune to enter upon a discussion of this subject.

In his paper, *An Experimental Study of Direct and Indirect Faradization of the Digestive Canal in Dogs, Cats, and Rabbits*, Meltzer arrives at the following conclusions: "The mucous membrane of the digestive canal offers a considerable resistance to the penetration of the faradaic current to the muscular coat; the greatest resistance is found in the mucous membrane of the stomach. The percutaneous and the direct faradization of the stomach or the intestines can not produce any contraction in these parts.

"My statements have reference only to the animals I experimented with. However, abdominal surgery might offer an opportunity to test their validity for the human being."

In perusing Dr. Meltzer's paper the following three points are somewhat startling:

1. In studying direct electrization of the stomach on animals—in which one electrode was situated within the viscus, the other at the serosa—this investigator did not

\* S. J. Meltzer. *New York Medical Journal*, June 15, 1895.

get any contraction whatever of the stomach, even if the faradaic current was very strong and if the two electrodes were not very far apart. (If the electrodes were directly opposite each other, then a strong current produced weak contraction.

2. In faradizing the gastric serosa with a bipolar electrode, Meltzer produced contractions only in the pyloric portion of the stomach, whereas the fundus of the organ remained *inert* even when the current was very strong.

3. The resistance of the gastric mucosa, according to Meltzer, is different from that of all other mucous membranes, being here very great.

While the first two points have direct reference to experiments on animals, the accuracy of which can only be ascertained by similar trials on animals, the third point is merely theoretically constructed, and, as it appears to me, on a false basis.

In contrast to Meltzer's experiments on animals I will report some of my own investigations, which I copy from my record book.

*Experiment I; July 2, 1895.*—Frog fastened with nails to a board; abdomen opened. Stomach filled with food. One electrode (consisting of a fine rubber tubing through which runs a thin wire; the tubing has one or two small openings near the end while its mouth is occluded) is introduced through the mouth into the stomach, while the other electrode (consisting of smooth metal about one millimetre and a half in thickness) is held over the gastric serosa. As soon as a faradaic current is sent through the electrodes the stomach contracts at the point situated underneath the outer electrode; the zone of contraction is formed by a line which is perpendicular to the greater curvature and extends over the entire width of the stomach; no contraction of the body visible; if the outer electrode is placed on any part of the body (leg or abdominal wall), then the faradaic current produces contractions of the body, while there is apparently nothing visible with regard to the stomach.

*Experiment II; August 13, 1895.*—Frog; the stomach does not contain any food. One electrode within the stomach, the other applied at the serosa; if the outside electrode is large, the faradaic current produces contractions of the whole body; if it is small, a constriction of the stomach appears beneath the outward electrode.

Stomach opened; both electrodes applied at the mucosa, the distance between them being 0.5 to 0.6 cm.: faradaic current produces contractions of the whole body.

The stomach is resected above the cardia and below the duodenum and removed from the body. If both electrodes touch the mucosa and the faradaic current is made to pass, a slow raising of the gastric walls becomes noticeable and the gastric volume becomes appreciably smaller.

If one electrode touches the gastric mucosa, while the other is applied at the serous coat of either the stomach or the duodenum, the faradaic current produces a constriction corresponding to the place at which the outward electrode is held.

*Experiment III; August 15, 1895.*—Frog; stomach empty. One electrode within the stomach, the other

applied at the serosa. The faradaic current produces constriction of the stomach at the place corresponding with the outside electrode, and at the same time contractions of the body. The position of the electrodes being the same, the galvanic current (3 MA.) effects a very pronounced contraction of the stomach at a place corresponding to the outside electrode; this contraction lasts for some time after the current has been interrupted.

The stomach is opened; both electrodes are held at different places of the gastric mucosa; the faradaic as well as the galvanic currents produce contractions of the body; the galvanic effects a contraction of the stomach which persists for some time after the current has been interrupted.

If the stomach is cut out and removed from the body, faradization (one pole being in the stomach, the other applied at the serous coat) always produces a constriction at a place corresponding to the outside electrode, while there is no marked change when both poles touch the mucosa. Galvanization produces raising and rolling up of the stomach if both poles touch the mucosa; while if one touches the mucosa and the other the serosa, there is an extensive contraction at the outside pole. The contraction lasts for some time after the current has been interrupted.

*Experiment IV; July 14, 1896.*—Frog (five weeks without food). One electrode within the stomach, the other applied at the serous coat; the faradaic current produces a contraction of the stomach at a place corresponding to the outside electrode. The stomach is opened and one little piece of Congo and litmus paper inserted in the stomach. Faradization for one minute, the electrodes being in the same position as just mentioned, did not change the color of either the Congo or the litmus paper.

The stomach being cut out and removed from the frog, shows a contraction of the organ upon direct faradization (one pole within the stomach, the other applied at the serous coat).

*Experiment V; July 15, 1896.*—Frog; stomach not containing any food. One electrode within the stomach, the other held over the serosa of the small intestine; the faradaic current produces constriction of the intestine at the place at which the electrode is applied.

The stomach is resected and removed from the abdomen; one electrode is placed at the mucosa, the other at the serosa; the faradaic current produces constriction of the stomach at the outside electrode.

If the stomach is put on one of the frog's legs and one electrode applied to the gastric mucosa while the other is held over any part of the frog's body (leg, abdominal muscles, or skin), the faradaic current produces contractions of the leg over which the stomach is situated.

*Experiment VI; July 22, 1896.*—Rabbit under chloroform anaesthesia. The abdomen opened and the stomach pushed forward. The bipolar electrode is held over the gastric serosa; the faradaic current produces a constriction of the entire width of the organ perpendicularly to the greater curvature. The entire gastric region, including the whole fundus, shows the same phenomenon.

The stomach is opened; one electrode is applied at the gastric mucosa while the other is placed over the serosa; the faradaic current produces a constriction at the outside electrode.

*Experiment VII; August 25, 1896.*—Rabbit under

chloroform anæsthesia. Abdomen opened; upon touching the gastric serosa with the electrode (without any current) a slight contraction of the stomach is visible. Applying the bipolar electrode at the gastric serosa, a weak faradaic current produces a more pronounced constriction of the stomach. If one electrode is applied to the gastric mucosa, while the other is held over any part of the serosa, the faradaic current effects a considerable constriction at the outside electrode.

*Experiment VIII; August 26, 1896.*—Rat under chloroform anæsthesia; abdomen opened.

1. The bipolar electrode is applied at the gastric serosa in the fundus region; a weak faradaic current produces a strong local contraction. If the bipolar electrode is held over the serosa in the middle of the stomach, the faradaic current evokes a somewhat weaker contraction.

2. Stomach opened. One electrode within the stomach, the other applied at the serosa in the fundus region; the faradaic current produces a strong contraction; if the outside electrode is held in the middle of the stomach, the contraction is slighter.

3. One electrode within the stomach, the second touching the serous coat of the duodenum or small intestine; the faradaic current invariably produces a contraction at the outside electrode.

*Experiment IX; August 26, 1896.*—Rat. The experiments mentioned under VIII are repeated, and the results are the same as described.

The stomach, if cut out and removed from the body, shows for a short period the same phenomena under the influence of the faradaic current as when in the body.

*Experiment X; September 2, 1896.*—Frog; abdomen opened. The rubber electrode within the stomach, the other applied at the gastric serosa. The faradaic current produces a contraction (considerable constriction) at the outside electrode. The latter being applied at different spots between the cardiac and pyloric portions of the stomach shows the same phenomenon. The position of the electrodes being the same, a weak galvanic current (1 to 2 MA.), lasting only half a second, produces contraction at the outside electrode; this contraction frequently assumes a peristaltic character.

The stomach is cut out and removed from the body; then it is opened. Both electrodes applied at the mucosa produce on faradization a peristaltic contraction rolling up the stomach. If one electrode is applied at the mucosa, while the other is placed at the gastric serosa, the faradaic current effects a contraction at the electrode held at the serous coat.

The galvanic current produces contraction, no matter whether both electrodes are applied at the mucosa, or one at the mucosa and the other at the serosa.

If small pieces of litmus and Congo paper are placed on the gastric mucosa and the faradaic current is applied to the stomach, the litmus paper turns slightly red, which the Congo is not changed.

*Experiment XI; September 2, 1896.*—Frog; abdomen opened. The stomach is small and empty. The experiments described under X are repeated; the same phenomena appear as above mentioned, although slightly less marked.

*Experiment XII; September 8, 1896.*—Frog; abdomen opened. The stomach is found filled with grass. One electrode within the stomach, the other applied at the gastric serosa; the faradaic current produces but weak contractions at the outside electrode.

The stomach is cut out and removed from the body;

then it is opened and emptied of its contents. The faradaic current, if both electrodes are applied to the serosa, produces contraction; if both poles are on the mucosa, slight rolling up of the stomach.

The galvanic current effects, if both electrodes are applied at the gastric mucosa, a strong peristaltic contraction. The same phenomenon takes place if the galvanic current is applied, one electrode touching the mucosa, the other the serosa.

*Experiment XIII; September 12, 1896.*—Frog; abdomen opened. The gastric electrode is within the stomach, while the other is held over the serosa. The faradaic current produces simultaneous constriction at the outside electrode. This refers to the fundus as well as to the pyloric portion of the stomach. The electrodes being in the same position, the galvanic current produces a very pronounced local contraction; the latter begins about two to three seconds after the current has passed, and is soon followed by peristaltic contractions of the stomach.

At the outside electrode, at which spot the local contraction originates, the stomach grows very pale, and remains in this state for about two to three minutes. If both electrodes are applied at the gastric serosa, the faradaic current produces a medium-sized contraction; while the galvanic current effects a very strong local contraction which is frequently accompanied by a peristalsis of the organ. Both electrodes being applied at the mucosa, the faradaic as well as the galvanic currents produce either a rolling up of the stomach or a contraction, although occasionally this phenomenon may be missing.

*Experiment XIV; September 13, 1896.*—Frog; abdomen opened. Both electrodes are applied at the gastric serosa; the faradaic current produces a contraction. The galvanic effects a very strong contraction; it appears two to three seconds after the current has passed and produces a considerable constriction of the stomach for quite a time (two or three minutes).

If the rubber electrode is within the stomach and the other is applied at the gastric serosa, the faradaic current produces simultaneous contraction at the outside electrode (the entire stomach, including the whole of the fundus, shows the same phenomenon). The position of the electrodes being the same, the galvanic current effects a very considerable constriction of the stomach (which part becomes decidedly pale) for quite a time. The stomach is cut out and removed from the body, but not opened.

Both electrodes applied at the serosa; the faradaic current produces contraction, no matter whether the electrodes are held at the fundus or at the pyloric part of the stomach. The galvanic current produces strong contraction persisting for quite a while.

(This phenomenon also refers to the whole stomach, fundus included.)

*Experiment XV; September 15, 1896.*—Frog; abdomen opened. One rubber electrode within the stomach, the other at the gastric serosa; the faradaic current produces a contraction. If the stomach is covered with the abdominal wall and the other electrode applied at the skin, the faradaic current produces either no contraction whatever of the stomach, or a slight one; while there are always contractions of the abdominal muscles.

If the stomach is severed from the body and put on the frog's abdomen, while one electrode is applied to the gastric mucosa and the other at the frog's leg,

the faradaic current, after an application of several seconds, produces visible peristaltic contractions of the stomach. This experiment was repeated several times with the same result. The peristaltic contraction persists for about twenty to thirty seconds after the current has been interrupted.

*Experiment XVI; September 15, 1896.*—Frog; abdomen opened. The rubber electrode within the stomach, another ordinary electrode applied in the rectum; the faradaic current produces contractions of the entire body, while there are no contractions visible either in the stomach or in the intestines.

If one electrode is applied at the rectum and the other held over the serous coat of either the stomach or the small intestine, the faradaic current invariably produces a contraction at the outside electrode.

*Experiment XVII; October 11, 1896.*—Small dog, about four months old, is chloroformed, the abdomen opened, and the stomach exposed. The latter is found in an empty state and does not show any peristaltic contractions. The bipolar electrode is applied at the serosa of the fundus; a weak faradaic current produces a local constriction which is soon followed by a peristaltic contraction. The entire region of the fundus discloses the same phenomenon. If the bipolar electrode is applied at the serosa of the pyloric portion of the stomach, the faradaic current produces contractions of a more intense nature. The stomach is opened; one electrode is held at the gastric mucosa, the other at the serosa (fundus); a weak faradaic current produces a light peristaltic contraction.

From the above-cited experiments it is apparent that in rabbits, rats, dogs, and frogs the faradaic current produces contractions of the stomach under the following conditions:

1. If a bipolar electrode is applied at any part of the gastric serosa (including the fundus).
2. If one electrode is held within the stomach and the other applied at any part of the gastric serosa.
3. If one electrode is within the stomach and the other applied to some other part of the body (leg, arm) which is not too far away from the stomach, a faradaic current of medium strength, lasting twenty to thirty seconds, produces peristaltic contractions of the stomach in addition to the contractions of the part at which the outside electrode is held.
4. The bipolar electrization of the gastric mucosa produces peristaltic contractions of a lower degree.

All four statements have also reference to the galvanic current, with the only difference that with the latter the contractions of the stomach appear somewhat later, are considerably stronger, and occasionally accompanied by peristaltic movements and last longer.

My experiments are thus not in harmony with the two statements of Meltzer's above mentioned, namely that:

1. Direct faradization of the stomach (one electrode within the stomach, the other applied at the gastric serosa) does not produce any contraction.
2. Faradization with the bipolar electrode of the serous coat of the fundus does not produce any contractions.

I now pass to Meltzer's third statement, that the gastric mucosa offers such great resistance (more than any other mucous membrane) to the penetration of the faradaic current. This statement is entirely hypothetical. Meltzer based his theory of the great resistance of the gastric mucous membrane upon the fact that faradization with the bipolar electrode applied to the gastric mucosa produced either no contractions of the stomach whatever or very slight ones.

Meltzer explains this phenomenon by assuming that the current *can not* penetrate the mucosa and reach the muscular layer of the stomach; for this reason there is no contraction.

It appears to me, however, much more probable and natural to presume that the gastric mucous membrane is a very good current conductor. But just for this reason the current, if both poles are at the mucosa, will run merely through this membrane and not reach the muscularis. The electric current, as is well known, always takes the shortest path, the one which offers least resistance.

Leaving theoretical explanations aside, I have measured the resistance which the gastric mucous membrane of man represents, as may be seen from the following experiment:

*August 8, 1896.*—Morris S., a healthy man of about thirty-eight years, takes one glassful of water and swallows the deglutible electrode; the other electrode (an ordinary sponge electrode two centimetres and a half in diameter) is applied at the epigastrium.

A very weak galvanic current is now made to pass between the two electrodes, and the resistance between the gastric mucosa and the skin measured with the Wheatstone bridge. It amounts to 6,800 ohms.

If one electrode is applied at the epigastrium while the other is placed at the back, somewhat to the left of the seventh dorsal vertebra, and a weak galvanic current made to pass through the electrodes, the resistance amounts to 22,000 ohms.

This clearly shows that the gastric mucosa does not offer any great resistance to the galvanic current. The gastric mucosa can not act differently toward the faradaic current.

All my experiments mentioned on animals tend to show that electrization of the stomach produces contractions of this organ. The last experiment on man shows that there is least resistance if one electrode is within the stomach and the other held at the epigastrium.

With regard, however, to the therapeutic efficacy of intragastric electrization, I do not believe that the same consists merely in producing contractions of the stomach, and fully agree with the following remarks of von Ziemssen: \* "The belief that the principal effect of gastric electrization consists in producing contractions of the muscles of the stomach and effecting a

\* H. von Ziemssen. *Die Electricität in der Medizin*, 1887, p. 445.

diminution of the size in gastrectasia does not in its main points harmonize with my own view. For I consider the influence of the current upon the secretory, vasomotor, and sensitive nerves as much more important and of practically higher value than its bearing upon the motor sphere."

Empirical knowledge is, I think, in perfect accord with this statement. For every one who has occupied himself sufficiently with intragastric electrization has undoubtedly seen its beneficial effect in the most varied affections of the stomach (principally of a functional character). I therefore do not hesitate to again warmly recommend direct electrization of the stomach as one of the most efficient and valuable remedies at our command.

#### ON THE TREATMENT OF SCIATICA BY MASSAGE.

By GUSTAF NORSTRÖM, M.D.

THE sciatic nerve is the greatest nerve of the body; it serves to innervate the muscles and the skin of the posterior part of the thigh, the whole leg, and the foot. The affection of this nerve presents itself under two forms, that of neuralgia and that of neuritis. The acute variety is caused by cold and traumatism; the other variety is likewise caused by traumatism (violent blows, prolonged improper position), by compression (tumors, luxation, fractures, pregnancy), by rheumatism and hysteria.

Neuritic sciatica may have the same origin as the neuralgic form. Its treatment is the same as that of neuralgic sciatica. The diagnosis is, as a rule, very easy. We must always seek the painful characteristic points, of which some may be absent in the special case. Generally speaking, the course of the whole nerve, or but a portion of it, is more or less painful to pressure according as the affection is of an acute or chronic character.

The most frequent cause of sciatica is rheumatism. Now, rheumatism produces in many cases a special myositis which comes on either before or after the nerve itself is affected. This myositis presents on palpation all degrees of muscular inflammation from simple puffiness to osseous induration of the muscular fibres.

I have very carefully explored all the muscles situated in the course of the sciatic nerve and in its neighborhood, and to my great surprise only one of them seems to be the favorite seat of the myositis; it is the *glutæus medius*, and particularly that portion of it which corresponds to its upper insertion. If we follow, however, the course of the nerve downward, we notice sometimes new deposits in the calf on a level with the peroneal muscles; these deposits may extend along the entire length of the muscle, but their maximum development is most often found toward the lower insertion. This explains, in my opinion, the pain which

persons affected with sciatica often complain of in the neighborhood of the external malleolus.

I have here briefly—that is to say, *en passant*—referred to the phenomena which accompany sciatic neuralgia, phenomena which may vary infinitely in intensity. It is difficult to determine which one of these two phenomena, neuralgia or myositis, is first produced. Sometimes they are simultaneous, the same cause—namely, rheumatism—provoking both of them. At other times, from the beginning, the nerve alone seems to be affected, but the muscle or the muscles are not long before being taken in their turn. Finally, in certain cases I have ascertained that the *glutæus medius* was alone affected, and that its inflamed state was sufficient to produce all the symptoms which are generally attributed to sciatica alone. This last fact may account for our being in many cases led into error, and, if we were to diagnosticate from its first appearance the inflammation of the *glutæus medius*, we should, by impeding its further development by an appropriate treatment, prevent the propagation of the irritation to the sciatic nerve.

In these cases a real compression on the part of the inflamed muscular fibres may be produced; a compression analogous to the one observed in cases of tumors or foreign bodies pressing on the same nerve. I have had to treat a certain number of cases in which I only used massage on the muscle itself, without paying attention to the nerve.

In one person among others laid up for nearly six months, in whom all the classical means had been employed, I was able to obtain by this procedure alone complete cure in less than five weeks. In this case the sciatic nerve did not present more than physiological sensibility on pressure, but in pressing on the muscle in the neighborhood the invalid screamed aloud and jumped up in the air, to the great astonishment of the patient himself and the physicians who were called in consultation.

These myositides, as well as sciatic neuralgia itself, are acute; then they may be chronic, or appear to be chronic, from the very onset (*chroniques d'emblée*).

I publish these observations in order to attract the attention of physicians to this peculiarity, which is most often unobserved, and which nevertheless plays an important part as regards the treatment. How many cases of sciatica are not cured, because one has not taken into consideration the possible presence of a myositis developed in the neighborhood of the nerve! Moreover, it is well to remember that this muscular inflammation may exist in the beginning only in the form of a puffiness, appearing very slight to the touch, and very often difficult to discover to the non-practised finger. In that state a rapid and definitive cure may be obtained.

*Treatment.*—I have already mentioned in my book on massage (*Traité du massage*) that sciatica is one of

those diseases in which we obtain by means of massage the most favorable results, and this not only, as it is generally believed, in the chronic cases, but also more especially in the acute ones.

If we consider, moreover, that myositis is always cured by massage, we may be easily convinced that the most efficacious treatment in sciatica (idiopathic or not) is massotherapeutics.\*

I will not here enter upon the way of performing massage in sciatica. I have described it in detail in the work alluded to. I shall only mention that, when the diagnosis is made certain that we have to do with a single or concomitant myositis, we must be careful to massage the affected muscle by exactly following the direction of its fibres. One is very often obliged to begin with a rather prolonged *effleurage*, so as to allow the patient to bear a more powerful and deeper massage later on.

I have had to treat in this way during more than twenty years of practice about a hundred and fifty cases of sciatica; some of them were accompanied by gluteal or gluteal and peroneal myositis, some were not, and very few are the cases in which I have failed.

122 EAST THIRTY-FOURTH STREET.

## Therapeutical Notes.

**Eugenol as an Internal Antiseptic and Local Anæsthetic.**—Maurange (*Gazette hebdomadaire de médecine et de chirurgie*, November 15, 1896) regards eugenol as an antiseptic suitable for subcutaneous use in cases of pulmonary tuberculosis with cavities and in those of pulmonary gangrene. He thinks it has an elective action on tissues invaded by Koch's bacillus, and consequently ought to prove curative of lupus. The ordinary subcutaneous dose for an adult is from three to fifteen grains; six grains are enough to produce local anæsthesia for minor dental operations. The injection is but slightly painful if the solution is thrown in slowly. In from four to twenty minutes an anæsthetic zone appears about the puncture. The anæsthesia is of short duration. The author credits Meunier with this formula:

R Eugenol..... 45 grains;  
Heavy petroleum oil..... 1,500 "

M. Dose, a cubic centimetre.

The following formula is attributed to Moty:

R Eugenol..... 150 grains;  
Oil of sweet almonds..... 1,500 "

M. Dose, from a quarter to three quarters of a cubic centimetre in the treatment of lupus.

**Sodium Bisulphate in the Treatment of Hay Fever.**—

*The Journal des praticiens* credits the *Pharmaceutische Zeitung* with the following formula:

R Sodium bisulphate..... 1 part;  
Distilled water..... 500 parts.

M. To be used as a lotion for the nasal passages.

\* We make, of course, an exception in the cases where a mechanical cause is always acting on the nerve; as, for instance, pressure from tumors or osteitis or periostitis in the neighborhood.

## THE NEW YORK MEDICAL JOURNAL, A Weekly Review of Medicine.

Published by  
D. APPLETON & Co.

Edited by  
FRANK P. FORTER, M. D.

NEW YORK, SATURDAY, DECEMBER 12, 1896.

### PROTECTIVE INOCULATION AGAINST TYPHOID FEVER.

In a recent number of the *Deutsche medicinische Wochenschrift*, cited in the *Deutsche Medizinal-Zeitung* for November 16th, Professor R. Pfeiffer and Dr. W. Kolle, of the Berlin Institut für Infektionskrankheiten, give an account of their experimental researches on the question of the practicability of protecting the human subject against typhoid fever by injecting a product of the dead bacilli of the disease. For their experiments they chose persons in health, or at least those who had no fever, in whose cases there was a clear history of their never having had typhoid fever. Within a short time after an injection, commonly between two and three hours, the first signs of reaction appear, consisting of chills, giddiness, a feeling of malaise, and pain at the site of the puncture. The evening temperature rises to about 101.3° F., and the first night's rest is somewhat disturbed. On the following morning the temperature is still a little elevated, but soon falls to the normal point, and that is the end of the symptoms.

The authors conclude that one injection of a very small amount of the agent brings about a specific change in the blood which is recognizable after six days and reaches at least as high a grade as they have ever been able to observe in convalescents from the disease. They think it more than probable that the presence of specific substances destructive of bacteria in the blood of persons who have had typhoid fever accounts for the immunity that is known to be enjoyed by such persons. If this assumption is correct, they say, prophylactic inoculations with the dead culture may be expected to confer an immunity of the same degree and duration as occurs after the disease has been incurred in the natural way, and they hold that their position is justified by the results of Haffkine's analogous protective inoculations against cholera, which have stood the severest test in many thousands of cases.

The hope is expressed that these protective inoculations against typhoid fever may become of practical value under certain conditions, for example, in the face of a severe epidemic, for they may be managed easily and speedily by any medical practitioner without special preparations, provided he has at hand the material in

proper condition. The authors draw a striking picture of the saving of life that may result from this practice in time of war, when whole armies have often been decimated by this scourge. Finally, they mention the many previous trials of typhoid-fever cultures and their derivatives, such as those made by Brieger, Wassermann, Fränkel, and others, but remark that these were not for the protection of the healthy, but in the treatment of individuals already affected with the disease.

#### THE THYROID TREATMENT OF STUNTED GROWTH.

BEFORE the *Versammlung deutscher Naturforscher und Aerzte* held in Frankfurt on the Main last September Dr. Johann Julius Schmidt, of Frankfurt, read an essay on this subject, which he had briefly touched upon a short time before in a discussion at the Wiesbaden Congress für innere Medicin. Dr. Schmidt's paper is published in the *Therapeutische Wochenschrift* for November 15th. After referring to Virchow's observation, in 1883, on the relationship of rickets, cretinism, and dwarfing without any disease of the thyroid gland being recognized as at the bottom of the relationship, he goes on to say that the thyroid probably plays an important part in simple stunting of the growth, as well as in cretinism and infantile myxedema. A number of recorded examples of dwarfing associated with atrophy of the thyroid gland are cited, and the author adds that experiments on animals corroborate the idea of a direct connection between the two conditions, as well as the feasibility of effecting by thyroid feeding the restoration of normal growth checked by thyroidec-tomy. Among the interesting observations cited is one by Lang of a hen which, four months after having had her thyroid gland removed, laid an egg that weighed only about a tenth of what an average hen's egg weighs and had a shell as thin as paper.

As regards clinical observations, Dr. Schmidt gives brief notes of four cases in which he has resorted to thyroid treatment to overcome dwarfing in children. The first was that of a girl, thirteen years old, but of the size of a girl of ten, whose growth was restored by thyroid feeding for a period of eighteen months, followed by a five months' course of a daily tablet of Baumann's thyroiodinin. The second was that of a girl, fifteen years old, in size only a child of eleven, who, as the result of ten months' treatment with thyroiodinin, had gained in weight about ten pounds. The third was that of a boy, sixteen years old, but no larger than an ordinary boy six years of age, who after a six months' course of treatment with English thyroid

tablets had grown more than two inches in stature and gained over ten pounds in weight. The fourth was that of a seven-year-old girl so small that her four-year-old brother exceeded her in height. After she had taken a Baumann's thyroiodinin tablet daily for four months it had been found that she had grown two thirds of an inch taller and was more than two pounds heavier. This was not quite satisfactory to Dr. Schmidt, and he ordered two of Engelhardt's thyroid-gland tablets to be taken daily. Not enough time had elapsed since his making this change to enable him to report on the result. These observations seem to warrant the expectation of our overcoming an abnormal condition that has always been looked upon as beyond the reach of therapeutics.

#### MINOR PARAGRAPHS.

##### FORMALDEHYDE FOR THE DISINFECTION OF RAILWAY CARS.

MAURIAC (*Journal de médecine de Bordeaux*, 1896, No. 33; *Centralblatt für innere Medicin*, November 21, 1896) recommends for preventing the propagation of infectious diseases by railway cars the use of formaldehyde vapor generated by burning methyl alcohol in contact with air and incandescent platinum. He describes a lamp that has been devised for this purpose.

#### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 8, 1896:

DISEASES.	Week ending Dec. 1.		Week ending Dec. 8.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	28	9	43	14
Scarlet fever.....	113	9	105	5
Cerebro-spinal meningitis...	3	2	4	3
Measles.....	89	2	116	1
Diphtheria.....	261	30	245	40
Tuberculosis.....	122	81	149	97

**The Wilhelm Meyer Memorial.**—The following announcement has recently been made: The committee on the fund to erect a monument to the memory of Wilhelm Meyer, of Copenhagen, apportioned fifteen hundred dollars as the amount to be raised in America. About eight hundred dollars of this amount has been subscribed and forwarded. Dr. R. C. Myles, of No. 46 West Third-eighth Street, New York, has been appointed to act as treasurer of the fund, and it is earnestly desired that all who intend to aid in making good the American deficit will send him their checks at an early date.

**The American Medico-surgical Bulletin.**—It is announced that at the close of the year Dr. William H. Porter and Dr. Egbert H. Grandin will retire from the editorship, which will be assumed by Dr. Robert G. Eccles, who is well known as a contributor to medical literature.

**The Aiken Cottage Sanitarium.**—Dr. Charles F. McGahan announces the opening of the sanitarium for patients on December 10th. It is planned after the Adiron-

dack Cottage Sanitarium, under the care of Dr. E. L. Trudeau. It is a philanthropic work and is for men only who are in the first stage of pulmonary phthisis. To exclude the pauper class, a nominal charge of five dollars a week is made, which includes board, washing, and medical attention.

**The Society or Medical Jurisprudence.**—The one hundred and twenty-second regular meeting will be held on Monday evening, the 14th inst., at which Dr. Theodore K. Tuthill will read a paper entitled *Remarks on the Coroner's Office, the Character and Scene of its Work*.

**The Richmond Academy of Medicine\* and Surgery.**—At the last regular meeting, on Tuesday evening, the 8th inst., a discussion on *Residual Urine in the Urethra* was to be opened by Dr. Stuart McGuire.

**The City (Charity) Hospital.**—Dr. Thomas H. Allen\* has been appointed a consulting surgeon.

**Changes of Address.**—Dr. W. W. Fullerton, from Boston to Brockton, Massachusetts; Dr. James Stuart, to No. 1226 Fourteenth Street, N. W., Washington.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from November 29 to December 5, 1896:*

WILSON, WILLIAM H., First Lieutenant and Assistant Surgeon, is granted leave of absence for thirty days, to take effect December 20, 1896.

**Marine-Hospital Service.**—*Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Thirty Days ending November 30, 1896:*

BROOKS, S. D., Passed Assistant Surgeon. Directed to assume temporary command of Port Townsend, Wash., Quarantine during the absence of Passed Assistant Surgeon W. G. Stimpson. November 10, 1896.

MCINTOSH, W. P., Passed Assistant Surgeon. Granted leave of absence for five days. November 5, 1896.

YOUNG, G. B., Passed Assistant Surgeon. Leave of absence extended two days. November 9, 1896.

STIMPSON, W. G., Passed Assistant Surgeon. To proceed from Port Townsend, Wash., to Angel Island, Cal., Quarantine for temporary duty. November 10, 1896.

NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for four days. November 9, 1896.

STEWART, W. J. S., Passed Assistant Surgeon. Granted leave of absence for three days. November 7, 1896.

BAILHACHE, P. H., Surgeon. Granted leave of absence for twenty-five days from November 18, 1896.

MAGRUDER, G. M., Passed Assistant Surgeon. Granted leave of absence for four days from December 5, 1896. November 28, 1896.

GARDNER, C. H., Assistant Surgeon. To proceed from Chicago, Ill., to Pittsburgh, Pa., for temporary duty, to arrive there on December 3, 1896. Upon completion of this duty to return to Chicago. November 23, 1896.

CUMMING, H. S., Assistant Surgeon. To proceed from New York, N. Y., to Southport Quarantine Station, Southport, N. C., for temporary duty. November 18, 1896.

#### Promotion.

CARMICHAEL, D. A., Passed Assistant Surgeon. Commissioned as Surgeon. November 14, 1896.

#### Boards Convened.

Board convened to meet in Washington, D. C., for the physical examination of an officer of the Revenue Cutter Service: Surgeon FAIRFAX IRWIN (chairman), Surgeon C. E. BANKS, and Passed Assistant Surgeon B. W. BROWN (recorder).

Board convened to meet in New Orleans, La., for the physical examination of an officer of the Revenue Cutter Service, Surgeon H. W. SAWTELLE (chairman),

Assistant Surgeon SEATON NORMAN, and Assistant Surgeon H. W. WICKES (recorder). November 27, 1896.

#### Society Meetings for the Coming Week:

MONDAY, December 14th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Boston Society for Medical Improvement; Gynecological Society of Boston; Microscopical Club of the Buffalo Society of Natural Sciences; Maine Academy of Medicine and Science (annual)—Portland; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

TUESDAY, December 15th: New York Academy of Medicine (Section in General Medicine); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Chautauqua (semiannual) and Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, December 16th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); Medical Societies of the Counties of Cortlandt (semiannual) and Tompkins (semiannual)—Ithaca, N. Y.; New Jersey Academy of Medicine.

THURSDAY, December 17th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement.

FRIDAY, December 18th: New York Academy of Medicine (Section in Orthopaedic Surgery); Brooklyn Medical Society; Baltimore Clinical Society; Chicago Gynecological Society; St. Louis Academy of Medical and Surgical Sciences.

SATURDAY, December 19th: Clinical Society of the New York Post-graduate Medical School and Hospital; St. Louis Medical Society.

## Births, Marriages, and Deaths.

### Married.

BAZET—WALLIS.—In Houma, Louisiana, on Wednesday, November 25th, Mr. Théophile F. Bazet and Miss Helen Gertrude Wallis, daughter of Dr. Hugh M. Wallis.

ECKFORD—RICE.—In Waynesboro, Mississippi, on Wednesday, December 2d, Dr. J. W. Eckford and Miss Mary Rice.

ERDMON—EDGAR.—In Jeanerette, Louisiana, on Monday, November 30th, Dr. T. A. Erdmon and Miss Caroline Edgar.

IRION—EGAN.—In Shreveport, Louisiana, on Thursday, December 3d, Dr. C. H. Irion and Miss Mary C. Egan, daughter of Dr. James C. Egan.

SAUTER—PLATTSMEIER.—In New Orleans, on Thursday, December 3d, Dr. Emile Sauter and Miss Eloise Plattsmier.

STIRLING—MANSTR.—In Baton Rouge, Louisiana, on Wednesday, December 9th, Dr. Louis Grey Stirling and Miss Alma Boatner Mansur.

### Died.

ARNOLD.—In Rockland, Rhode Island, on Wednesday, December 4th, Dr. John A. Arnold, of Brooklyn, aged fifty-one years.

ELLIS.—In New York, on Thursday, December 3d, Dr. John Ellis, in the eighty-second year of his age.

LETCHER.—In Dallas, Texas, on Monday, November 30th, Dr. Joseph S. Letcher, in the forty-seventh year of his age.

WOODRUFF.—In Pine Bush, N. Y., on Tuesday, December 1st, Dr. William H. Woodruff, in the sixty-sixth year of his age.

## Proceedings of Societies.

### SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

*(Meeting of October 7, 1896.)*

The President, Dr. LUCIUS W. HOTCHKISS, in the Chair.

**The President's Inaugural Address.**—Dr. HOTCHKISS expressed his sincere appreciation of the great honor conferred in electing him president of this most honorable society. For this mark of confidence and esteem, the highest gift in the power of the society to grant, he expressed his sincerest thanks.

In accepting the honored position of president of this society, he said, and fully impressed with its dignity and responsibility, he was also conscious of the great amount of work which its acceptance entailed. The officers of the society were its servants, and much depended upon their faithful discharge of duty. He was proud, moreover, to have associated with him as vice president one who honored the office, and who had done so much to further the best interests and traditions of the organization.

In assuming the chair and recalling how much has been accomplished by the energetic officers of former years, Dr. Hotchkiss said that he could not but feel his own unworthiness, and should many times have to ask indulgence, and should always rely on hearty co-operation in furthering the progress of the good work begun.

It was his good fortune, he said, to have been identified with the Society of Alumni of Bellevue Hospital from its birth; to have been one of the committee on organization which reported September 21, 1886, a constitution and by-laws which were adopted.

He had watched with the greatest joy and pride its progress from a lusty infancy to a promising youth, and felt justly proud of his membership in such an organization. Looking backward over the first decade of its history, he was amazed by the steady and marvelous growth from small beginnings.

Organized for the object of promoting the advancement of medicine and surgery and social intercourse among its members, it had singularly prospered. Its influence was felt among alumni of Bellevue everywhere.

The great reunions which had occurred from time to time had been the means of bringing together old Bellevue men from different parts of the world, of fostering good fellowship and heightening the *esprit de corps* among the many children who claimed old Bellevue as their Alma Mater. From an original membership of nineteen which had by the end of the first year reached forty-one, the roll had increased rapidly until in 1894 it numbered one hundred and ninety-nine members. At the present date there were two hundred and twenty-three, which number included resident, non-resident, associate and permanent associate, and honorary members. The early meetings in the winter of 1886 were held in Carnegie Laboratory, where, in the midst of dusty collections of various pathological specimens and growing potato cultures of the cholera bacillus, and enlivened and sustained by the presence of a small keg of beer and a plate of sandwiches, the members passed long evenings in which science, sandwiches, and smoke were joyously mixed.

At this time, though the membership was limited to graduates of not longer than ten years' standing,

they rejoiced in their name of The Society of the Alumni of Bellevue Hospital.

As the membership rapidly enlarged the society sought better quarters, until, at the great gathering at the Cambridge, some six years ago, it began like a young giant to appreciate its great strength and marvelous growth. From that time its growth had been healthy and steady, and the meetings had been full of interest.

A few years ago, continued Dr. Hotchkiss, a medical journal had sharply criticised the society for styling itself The Society of Alumni, etc. The researches of one of its most honored and learned members, however, had clearly proved that etymologically, at least, the society's name was correct, for, as he skillfully pointed out, the members were all alumni—i. e., nourished by a common mother. He pointed out that the word *alumnus* was derived from *alere*—to feed, to nourish. And were they not fed, if not nourished, forsooth, by their Alma Mater? And having been so fed, they all felt that they represented the survival of the fittest, The Society of Alumni of Bellevue Hospital.

They looked backward upon the first decade of their history to the struggles of their young society, and its progress by rapid strides to the foremost position among the great clinical societies of the great city. They were all proud of her. Standing on the threshold of a new year, said Dr. Hotchkiss, and looking back on a glorious past, they should press forward earnestly to the attainment of a greater growth and usefulness. In Dr. Carlisle's account of Bellevue Hospital, published in 1893, was a list of 427 alumni of Bellevue then living and practising. Of this number, 210 lived in New York city, 56 lived in the State, and 161 were scattered in other States and countries. The speaker thought that every effort should be made to increase their numbers. The objects of the society appealed to every worthy son of Bellevue. Every Bellevue man should be interested in the work and every one who was worthy should be upon the rolls.

The tendency of all medical societies was to become, after a time, more or less apathetic, to leave the active work to a few. Here it should not be so. The members were all interested, and should all be workers.

The society wanted the young men and the old men.

The floor was open to all, and the younger men fresh from the work of the wards should be encouraged to use it.

With all workers and no drones in the hive, with all doing active service in the welfare of the society, it would easily accomplish a much greater work in the future than in the past, not only in the way of encouraging social intercourse and good fellowship among men who seldom met, but in the advancement of medicine and surgery, and by adding its share to the great source of human knowledge.

*(To be concluded.)*

## Book Notices.

**Diseases of the Stomach.** A Text-book for Practitioners and Students. By MAX EINHORN, M. D., Instructor in Clinical Medicine at the New York Post-graduate Medical School and Hospital, etc. New York: William Wood & Co., 1896. Pp. xiv+478.

THE appearance of this book is of some significance in so far as it is the first original work of its kind—a

monograph on diseases of the stomach—published in America.

When we glance over the medical literature of the past and of the present generation we find that there exists a tendency to write more and more in a clear and easily comprehensive style. We notice also that books written in such a style as by itself to afford pleasant reading are more appreciated than those which, although of perhaps the same scientific standard, are composed in artificial and complicated phraseology.

It is impossible to exaggerate when we speak in praise of the clear, concise language, a language of almost classical simplicity, which presents itself in Dr. Einhorn's book.

Another pleasant feature is noticeable and will be observed by those who are in the habit of reading certain German scientific publications—the absence of *ἀλλοφάνης* and other words constructed by means of the lexicon of some foreign language, words which sound very learned to some, but in fact are distasteful.

Dr. Einhorn was one of the first in the field, in this country, when diseases of the stomach began to be treated as a specialty. He has devoted many years of a very active life to the study of this specialty, and has enriched our science with a number of original researches, observations, and inventions of lasting value. Quite properly, then, has this work been looked for with exceptional interest, and those who expected a book of scientific and of eminently practical value have not been deceived.

The first chapter, on the anatomy of the stomach and the physiology of digestion, is a masterpiece of precision, giving exactly what the practitioner needs to know, no more and no less. In the second chapter, on methods of examination, we find a description of the author's own invention, the gastrodiphane. Among the many contrivances which have been presented by different authors none can compare with Dr. Einhorn's in simplicity and ease of application. Dr. Einhorn's instrument has none of the drawbacks which characterize the others.

Under the heading of examination of ingesta only such methods are enumerated as have proved of most practical value and are the most reliable. Here, again, we have the description of one of Dr. Einhorn's own inventions which offers indeed many advantages—the stomach bucket. One can carry it in the waistcoat pocket and may use it when the tube is not at hand, where the examination with the tube is declined, or where for other reasons the use of the tube is forbidden. Another invention of Dr. Einhorn's is described which has for its purpose to ascertain the mechanical function of the stomach. It is the ingeniously constructed apparatus called gastrokinesograph, or gastrograph. By means of this apparatus the churning motions of the stomach may be demonstrated. It is probable that continued experimentation may prove this apparatus to be a means of diagnosing certain pathological conditions.

It almost goes without saying that the chapter on diet is a thorough treatise based on the scientific principles which are recognized at the present day. In the chapter on local treatment we read of the author's gastric spray apparatus, which has proved a valuable therapeutic agent in cases of erosions of the stomach, in some forms of chronic gastric catarrh, and in oversecretion and hyperacidity.

Perhaps the most popular of Dr. Einhorn's inven-

tions is his deglutible stomach electrode, by means of which direct electrization of the stomach is facilitated. Indeed, there are many instances in which by Dr. Einhorn's contrivance only do we succeed in availing ourselves of a therapeutic measure of great importance, the direct electrization of the stomach.

With special interest will be read the original and important observations on erosions of the stomach and also the chapter which treats of achylia gastrica. Here we feel indebted to the author for having brought facts to light which give us a better understanding of this affection, and for having shown how this condition may exist without depending on pernicious anemia.

One of the features of the book, not an unpleasant one, is the scarcity of prescriptions given. There are about twenty-four formulas in all. This is certainly progress in the right direction. Instead of the usual abundance of formulas we find the guiding, the reliable principles of therapeutics, and learn to apply them instead of learning a large number of prescriptions by heart. Not too much stress can be placed on this point. Especially will the student who reads Dr. Einhorn's book be thereby the more benefited.

The book commends itself to every student, every practitioner, and, not the least, to specialists of all the different branches. Each and every one of us is obliged to follow the progress in the specialty of the diseases of the stomach. Here we have all that is of importance set forth in a really attractive form. The book is a credit to American literature and will be appreciated as such both here and abroad.

*A Text-book for Training Schools for Nurses, including Physiology and Hygiene and the Principles and Practice of Nursing.* By P. M. WISE, M. D., Medical Superintendent, St. Lawrence State Hospital, etc. With an Introduction by EDWARD COWLES, M. D., Physician-in-chief and Superintendent of the McLane Hospital, Boston. In Two Volumes. New York: G. P. Putnam's Sons, 1896. Pp. xvii-247; vi-327.

It is indeed with a sense of relief that we have read this work, for when we look back upon the large number of "text-books on nursing," "aids to nursing," and books of similar intent that we have been compelled to read for criticism, and remember what utter trash, as a rule, these works have been, we confess to having had a considerable amount of skepticism as to whether a thoroughly commendable and systematic work upon nursing was among the present possibilities. Why it should be so difficult a task to write a satisfactory work of this sort we fail to see, but, with rare exceptions, the authors of such treatises manifest woeful ignorance of their subject or else presume to teach the student-nurse medical things which are far beyond her proper knowledge. The explanation of the matter may lie in the fact that the art of nursing has as yet few teachers who are competent to teach, for it is one thing to be an excellent practitioner of nursing or of another art, and quite another to demonstrate and teach it properly. Few medical men, we think, could wisely venture to expound this subject, and as for nurses themselves, we have too many examples of their incompetence. It is therefore almost with an involuntary "At last!" that we have read this book, for we have found it what it purports to be and what it should be, a thorough, systematic, and proper book for the use of the student-nurse and one, notably, which keeps "as near as possi-

ble to the neutral line between medicine and nursing" (preface).

The book is published in two volumes, a provision for its use in the two-years' course now generally demanded in training schools for nurses, and each volume contains thirty chapters, a provision for a weekly lesson for each of the usual thirty recitation weeks of the year. This arrangement is certainly an excellent one, and clearly renders the book more adaptable to the uses of most schools, while it does not in the least interfere with adaptation to other courses of different arrangement.

To describe minutely the field covered by the book would obviously be a lengthy undertaking and, too, one of no practical service. A brief description will amply suffice. Volume I deals with human anatomy and physiology as well as hygiene and, finally, the observation of symptoms. Volume II continues the theme and treats of therapeutic applications proper for the nurse's knowledge, as well as of morbid conditions and the information on them suitable for a nurse. The concluding chapters treat of pregnancy, labor, infantile nursing, and gynecological nursing, and are well in keeping with the rest of the work. The tone of the book throughout is commendable in the highest degree, and the nurse is provided only with information which is justly and properly hers, to the end that she may be a valuable and useful member of the community and not a nuisance. The book does not attempt to replace practical work and bedside training; on the contrary, it is merely complementary to them. It is not a book designed for self-education as a nurse (of the nursing-made-easy class), but simply and only for use in properly conducted training schools.

The clearness and the simplicity which mark its style are delightful, and the nurse who can not gain instruction, benefit, and pleasure from its reading must indeed be dull. We are in every way pleased with this work and may be pardoned if we show for it some unusual enthusiasm, for the matter which provokes it is unusual. The work has our cordial recommendation, and our only regret is that the illustrations should be so crude and therefore jar amid so much that is excellent.

*Water and Water Supplies.* By JOHN C. THRESH, D. Sc. (London), D. P. H. (Cambridge), etc. Philadelphia: W. B. Saunders, 1896. Pp. xv-431. [Price, \$2.25.]

To those interested in the matter of water supply—and necessarily the class must be a large one—we heartily commend this little work, for they will derive from it a great amount of valuable and reliable information.

The opening chapter treats of water, its composition and properties, and the six chapters which immediately follow discuss rain water, surface water, subsoil water, spring water, deep-well water, and river water respectively. These chapters are, indeed, in no essential unusual, but they are very able discussions of these most important matters. Chapter VIII presents a consideration of the quality of drinking waters, and Chapter IX deals with impure water and its effects upon health. There follow chapters upon the interpretation of water analyses, upon the pollution of drinking water, and upon the much-vexed question of self-purification of rivers.

The chapters next presented are the most valuable the book contains, and their contents are both well expressed and highly instructive. The purification of

water on a large scale is the subject of Chapter XIII, and domestic purification is that of Chapter XIV. The softening of hard water and the quantity of water required for domestic and other purposes are next discussed. Chapters XVII and XVIII, dealing with the selection of sources of water supply and wells and their construction, are of great importance and value. The concluding chapters treat of pumps, of the storage of water and its distribution, of the law relating to water supplies, and of the supply of rural districts and villages. An appendix deals chiefly with various sources of contamination and pollution.

To him whose care is the management of water supply the book will be of the greatest usefulness, and to all thoughtful and intelligent readers, not medical men and sanitarians alone, it will be both interesting and instructive.

*A Text-book of Special Pathological Anatomy.* By ERNST ZIEGLER, Professor of Pathology in the University of Freiburg. Translated and edited from the Eighth German Edition by DONALD MACALISTER, M. A., M. D., Linacre Lecturer of Physic and Tutor of St. John's College, Cambridge, and HENRY W. CATTELL, M. A., M. D., Demonstrator of Morbid Anatomy in the University of Pennsylvania. Sections I-VIII. New York and London: The Macmillan Company, 1896. Pp. xix-575. [Price, \$4.]

The appearance of the third English edition of this portion of Professor Ziegler's master work will be cordially welcomed by all English-speaking students of pathology. An American translation of the part of this work relating to general pathological anatomy was published in 1895, and the presentation of this additional part on special pathology leaves seven chapters of the complete work still inaccessible to readers who are unfamiliar with German. It is to be hoped that the complete translation will not be long delayed; in fact, the remaining chapters are said to be now in press. We are also promised by the same house a complete Anglo-American edition of uniform style, which will be welcomed, since the translators of the part on general pathological anatomy committed the blunder of omitting the bibliography, which forms an indispensable feature of the original work.

Of the contents of the present volume it is only necessary to say, as of all the work of this author, that they present everything that is definitely known about the subjects treated of. To accomplish this, the additions necessary to the last German edition (1892), and especially to the last English edition, have been such as to require the complete recasting of the text. The work of the translator has been uniformly excellent, and the publishers have prepared an elegant and very portable volume.

*The Tonic Treatment of Syphilis.* By E. L. KEYES, A. M., M. D., Late Professor of Dermatology, Syphilology, and Genito-urinary Surgery, Bellevue Hospital Medical College, etc. Revised Edition. New York: D. Appleton & Co., 1896. Pp. x-78.

In this, the second edition of Dr. Keyes's valuable little book on the tonic treatment of syphilis, the average practitioner will perhaps find the most satisfactory general guide to the management of this disease in the English language.

The former edition of the work has probably done more to mitigate the evils that follow injudicious and

too energetic treatment in this condition than any other American text-book. Dr. Keyes's views upon this subject, however, are well known, and need no indorsement.

The present edition gives the result of the author's accumulated experience, which has served to strengthen his opinion regarding the soundness of the views originally published twenty years ago.

*The Ready-Reference Handbook of Diseases of the Skin.*

By GEORGE THOMAS JACKSON, M. D., Professor of Dermatology in the Woman's Medical College of the New York Infirmary, etc. With Sixty-nine Illustrations. Second Edition, revised and enlarged. Philadelphia and New York: Lea Brothers & Co., 1896. Pp. viii-13 to 594. [Price, \$2.75.]

THE great success of the first edition of Dr. Jackson's book, and its consequent early exhaustion, have afforded the author the flattering opportunity of giving us a second edition rather on this account than by any vital need of its rejuvenation. It has enabled the writer, however, to add a considerable amount that is new, and by a careful revision to bring his book completely up to the present time. New sections have been added upon several forms of cutaneous disease.

Nineteen new illustrations have been inserted which add considerably to the value of the book. The large number of titles from foreign languages and the pronunciation of the various names, were features of the first edition which have proved as acceptable as they were then novel.

The part devoted to the subject of diagnosis is to be particularly mentioned as containing many valuable points, both for the practitioner and for the student; and Dr. Jackson's well-known *Dermatological Don'ts*, with which he concludes Part I, will always commend themselves from the combination of quiet amusement and common-sense instruction contained in their warnings.

## New Inventions, etc.

### A MODIFIED NASAL SNARE.

By SAMUEL GOLDSTEIN, A. B., M. D.,

ATTENDING SURGEON, NEW YORK THROAT AND NOSE HOSPITAL, ETC.

SINCE the introduction of the Jarvis snare, numerous modifications, *more or less costly*, have been made of the original instrument. One of the simplest, and also most practical, I have found to be that of Sajous.

With this instrument as a model, I have had added a smaller companion cannula for the application of a transfixion needle.

As clearly shown in the cut, no expensive additions have been made; on the contrary, the maker, George Ermold, has carefully adhered to my request, and has produced a simple, strong, easily cleansed, and practical instrument.

The addition of the finger rings affords the operator a firmer hold of the instrument.

166 EAST NINETY-THIRD STREET.

## Miscellany.

**Glycerite of Licorice.**—In the December number of the *American Journal of Pharmacy* there is an article by Mr. Joseph W. England in which he gives an account of some experiments undertaken by him to obtain a satisfactory liquid licorice preparation. Liquid preparations of licorice, he says, are generally the most popular products used to mask the taste of bitter and nauseous drugs, in spite of the fact that none of them are fully representative or free from objectionable features. The notoriously variable quality of commercial extract of licorice is well known. The fluid extract is acid from the resin dissolved by the alcohol of the menstruum used in making it. The official pure extract does not have the pure licorice flavor and is apt to become moldy. The purified extract of the *National Formulary* is the best product of all, but its merits are marred by a strawy taste, the probable presence of vegetable spores, and the absence of definite strength. That licorice root yields volatile principles is well known, and it is obvious, then, he says, that a satisfactory liquid licorice preparation should be one holding in solution all the desirable soluble proximate principles, free from acid resin or other undesirable products, of full odor and taste, and standardized to a definite strength. These results the author has endeavored to obtain by the following process:

Take of:

Powdered extract of licorice..	8 troy ounces;
Water.....	32 fluidounces;
Ammonia water.....	1 fluidounce;
Glycerin, a sufficient quantity.	

Sift the powdered extract of licorice upon the water and water of ammonia contained in a capacious agate-ware pan, dissolve as far as possible, and pour the mixture upon a specially prepared sand bed (to be hereinafter described) contained in a half-gallon glass funnel. Let it stand for twelve hours, or over night, collecting percolate. Then, with a small porcelain capsule, remove the gelatinized, starchy mass that has formed upon the surface of the sand bed. Add water and continue the percolation until the soluble matter in the bed has been practically washed out. Mix the percolates, note the volume in fluidounces, evaporate one fluidounce on a water bath to a constant weight, weigh, estimate the number of grains contained in the reserved percolates, and divide by two hundred and forty to obtain the number of fluidounces of a fifty-per-cent. by volume solution that can be made. Then, by means of a sand bath, carefully evaporate the reserved percolates down to *three fourths* of the estimated volume, and add sufficient glycerin to make up the volume. Care must be used, especially during the latter part of the evaporation, that the product should be frequently stirred and not be too highly heated, as it is then very readily scorched. If, during evaporation, turbidity should occur as a result of too long a heating, clearness may be restored with a few drops of ammonia water.

While the evaporation of percolates is proceeding, another lot of the licorice extract mixture may be percolated through the *same* sand bed, and the process duplicated, or a larger sand bed may be used and the process followed on a larger scale. Doubtless, when working on an extended scale, the sand bed could be made quite large; steam heat, with a vacuum apparatus, could be employed, and working details could be profitably modified.

Ammonia water is added to the licorice extract mixture to bring into solution the uncombined glycyrrhizin of the powdered extract. The excess of ammonia water is eliminated by the after-heating.

The success of the process, says Mr. England, depends upon the manipulation of the sand bed and the carefulness with which the percolates are evaporated. To prepare the sand for the bed, take fairly coarse washed bar sand, and remove sticks, stones, etc., with a No. 20 sieve. Clean the sieved portions thoroughly with washings of boiling water, and dry, heating strongly. To make the bed, place a flat piece of absorbent cotton, wetted on the under side, in the bottom of the funnel and fill the latter with the cleaned sand to within an inch or two of the top. If a larger glass funnel is used, it need not be filled quite so full, but, to a degree, the broader the surface of the sand bed used the better the results. Percolation begins quickly, but slows up in a short time. If the first portions of percolate are turbid, they should be returned to the funnel.

The gelatinized, starchy mass that is formed upon the surface of the sand bed is sometimes an inch or more deep. It is nearly black from the presence of a portion of the soluble principles of the extract. But the amount of the latter is of no practical moment, and is compensated for by the subsequent standardization. By removing the gelatinized mass before continuing percolation, the latter is made much more easy. With care, the same sand bed may be used for a number of operations.

With this formula, continues Mr. England, the mixed percolates obtained by him amounted to about forty fluidounces. More than this, he says, make no practical difference, as the solution is standardized, but it is desirable to have as small a volume as possible, in order to diminish the time of evaporation, and reduce the danger of an emphyreumatic product.

The powdered extracts used by him averaged forty per cent. of insoluble matter. The amount usually allowed by manufacturers is thirty-five per cent., but the percentage varies according to the age at which the roots have been gathered; the younger the roots the more starch they contain, and the more insoluble matter there is in the extract made from them. With a powdered extract of licorice containing more than forty per cent. of soluble matter dissolved in the quantity of water mentioned in the preceding formula, it is obvious that a denser solution would result, and it is probable that the formula given would need some modification—more water and a larger sand bed, for instance.

With regard to the standardization of the mixed percolates, says Mr. England, it is a simple matter. If there are forty-one fluidounces of percolates, and a fluidounce has been found to contain sixty grains of anhydrous extract, it is evident that there are twenty-four hundred grains of extract in the forty fluidounces reserved, a quantity sufficient to make ten fluidounces of a glycerite of licorice containing two hundred and forty grains to the fluidounce. Then, if the product is to contain twenty-five per cent. by volume of glycerin, it will be necessary only to evaporate the forty fluidounces to seven fluidounces and a half, and add the glycerin.

The product made in this way, continues the author, is a black syrupy liquid having the characteristic odor and taste of pure licorice. It is different in physical properties from the usual preparations, as it is free from any objectionable taste or ingredient, is stand-

ardized to a definite strength, and seems to have permanent keeping qualities.

**Tanosal, a New Preparation of Creosote.**—It appears from an article in the *Therapeutische Monatshefte*, summarized in the *Therapeutische Wochenschrift* for November 22d, that this new drug is a synthetical tannic-acid ester of creosote. It is described as an amorphous dark-brown, very hygroscopic powder having a faint odor of creosote. On account of its proneness to deliquesce, it can not be dispensed as a powder. It is on the market in the form of a watery solution and in that of pills. Each pill contains about five grains of tanosal, equivalent to three grains of creosote. On account of the ready solubility of tanosal, it is easily administered in water, and it is not irritating to sound mucous membranes; yet, because of its harsh taste, the solution should be freely diluted, a tablespoonful with half a glass of sweetened water.

Dr. G. Kestner, of the civil hospital in Mühlhausen, thinks that tanosal is better borne by the digestive organs than any other preparation of creosote. It seems to be excreted neither unchanged nor in the form of creosote. Kestner has used it in more than seventy-five cases. The usual dose is a tablespoonful of the solution, three times a day, gradually increased in some cases to double that amount. There have been instances in which patients have taken as much as nine tablespoonfuls in a day without any inconvenience. In three cases of tuberculous intestinal ulceration, however, the remedy gave rise to colic and diarrhoea, even in small doses. In many cases it became distasteful after being used for a long time, but generally the distaste was overcome.

Among the patients there were thirty-three with pulmonary tuberculosis, fifteen with acute bronchitis, eleven with chronic bronchitis, one with chronic broncho-pneumonia, five with bronchitis incidental to infectious diseases, and ten with simple catarrh of the throat and bronchi, and it was in the last-mentioned class of cases that the best results were obtained. Reduction of the bronchial secretion is the chief of its effects, and to accomplish such reduction it is at least equal to terpene. Its action is the greater the more recent the case, but even in cases of long standing it diminishes the expectoration and the dyspnoea. Like other creosote preparations, it sharpens the appetite. Children respond to it more readily than adults, and for them the amount to be taken daily is commonly a teaspoonful of the solution for each year of age. In phthisical cases it acts as well as any other preparation of creosote.

**Rhinitis as a Factor in Phlyctenular Ophthalmia, with its Therapeutic Consequences.**—At a recent meeting of the College of Physicians of Philadelphia Dr. B. Alexander Randall read a paper on this subject in which he said that among the many causative factors of phlyctenular conjunctivitis and keratitis, inflammatory affections of the nose must not be ignored; for they could frequently be demonstrated to be of prime importance. In the great majority of cases, hyperæmia and oversecretion of the nasal mucous membrane would be found more constant than eczema or any other of the more incidental accompaniments; and treatment limited to this alone would often bring about a cure quicker than could be effected by any local measures without it. Elaborate apparatus and skill were uncalled for. Mere illumination of the nares would usually show the condition, and simple sprays of alkaline and of oily solutions

could do much to relieve it. Calomel insufflation could be more valuable than in the conjunctiva, and, instead of the iodine being a bar to its use, its combination with mopping the pharyngeal vault with iodine could be especially efficacious. Dr. Randall said that the ophthalmologist must not neglect this field, which used to be his; and, unless he had some one at hand better prepared than himself to give it due care, he should stand ready to study and treat in his patients these simpler nasal affections.

In the discussion which followed the reading of this paper Dr. Ring stated that he had for nearly two years referred nearly all cases of phlyctenular conjunctivitis treated in his clinic at the Episcopal Hospital to the throat and nose department for nasal treatment.

Dr. Risley had been well satisfied with the results of rhinological treatment of obstinate cases.

Dr. de Schweinitz considered that in all these cases attention should be drawn to the condition of the nares. In his public clinics, when immediate nasal treatment had been impracticable, he had sterilized the nose as well as the eye by the simple remedies that he kept on hand for the purpose, and the results had been the happiest.

**Rheumatism Treated by the Local Dry Hot Air Method.**—At a recent meeting of the Harveian Society of London, a report of which is published in the *British Medical Journal* for November 21st, Dr. Knowsley Sibley presented a woman, twenty-six years old, who had been a complete cripple from rheumatism for nearly three years. Her mother and her mother's grandfather suffered from the same complaint. The patient had very fair health up to three years ago. She had never been laid up with fever or was there any cardiac lesion. She had been for many months under treatment at Bath, but without getting any better. She was sent up to London for treatment on September 30, 1896. On admission, the following note was made: "The patient has used a pair of crutches for two years, and can just manage to get about on the level with the aid of these; she can not get up or down stairs, wash or dress herself, or do her hair. She feeds herself with great difficulty, and only with a large spoon and fork, as she can not get either hand within several inches of her mouth. She can not rotate the elbows, which are nearly fixed at right angles. There is considerable thickening of the middle fingers of both hands, and grating and limitation of movements at the shoulder joints. The right knee is ankylosed nearly at a right angle; there is absolutely no movement of any kind to be elicited; the thigh and especially the calf muscles of this leg are much wasted; the patient can just touch the ground with the tip of the toes, but is unable to put any weight on the limb, and in fact can not raise it off the bed when lying on her back; there is constant pain of this joint; she wears a gutta-percha splint round it as a protection."

The localized hot-air treatment, continues Dr. Sibley, was begun on October 1st. After the second application it was possible to rotate the left elbow, and after the third the patient was able to see the palms of both hands, which she had not done for two years. After the sixth bath she was able to do her front hair, and after the tenth she was able to walk a few steps without her crutches, and there was distinctly some movement to be obtained in the knee joint. She had now had twenty-seven baths, and could get her left hand all over her face, head, and neck, and get up and down stairs

with ease. There was now a fair amount of movement in the right knee joint; the patient could flex and extend it some few inches. All these results had been obtained without at any time putting her under an anæsthetic and breaking down the adhesions, as was originally suggested; and at no time had she any pain or effusion in any of the joints under treatment. Before and after each application of the dry air, which was heated to a temperature of 260° F., the limbs were gently manipulated and massaged. She had been taking some syrup of the iodide of iron, and the bowels were regulated with Condal water.

**A Case of Recovery Twelve Hours after the Ingestion of an Ounce of Chlorodyne.**—The *Lancet* for November 21st publishes the following account of a case which came under the observation of Mr. Thomas Massie: The author was called one morning at 11 o'clock to see a man who was said to be dying from the effects of poison. He was a mechanic, forty-five years of age, was muscular, and looked strong. The previous afternoon he sent for an ounce of chlorodyne, took a few drops of it for a cough, and then went out for the evening. He returned home about 11 P. M. the worse for drink, and before going to bed drank all the chlorodyne, the empty bottle being found at his bedside when his wife made a fruitless effort to wake him up next morning about 10 o'clock. The author found him deeply narcotized. The pupils were much contracted, the breathing was slow, labored, irregular, and noisy, and the pulse was thready and weak. The skin was clammy, the limbs were cold, and the face was cyanosed. Mr. Massie injected two-fifteenths of a grain of apomorphine hypodermically and applied strong solution of ammonia to the nose, but without any result. He then injected about a pint of strong hot coffee mixed with eight drops of solution of sulphate of atropine (B. P.) into the bowel. This produced a marked improvement in the color of the face, the pulse, and the respiration. He now introduced the stomach siphon and washed out the stomach with a quart of strong hot coffee. The author states that he could detect the odor of chlorodyne in the washings. He repeated the process, using the same quantity of coffee. The patient by this time began to show signs of consciousness. Strong solution of ammonia was now assiduously applied to the nose with excellent results. Soon the patient was able to get out of bed and, supported on either side, walked about the room for two hours, drinking large quantities of coffee meanwhile. At the end of six hours, although drowsy, he was out of danger, and next morning he was nearly well.

**The Legal Value of Dying Declarations.**—In the *Boston Medical and Surgical Journal* for November 26th Dr. Daniel March, Jr., of Winchester, Massachusetts, remarks that dying declarations, as defined by the American and English cyclopædias, are statements of homicide made by the victim under the solemn belief of impending death. The effect of such belief is regarded as equivalent to the sanctity of an oath. Declarations so made are substitutes for sworn testimony, and they must be such narrative statements as a witness might give on the stand if living.

The importance to the physician or medical examiner of a knowledge of the subject of dying declarations, he says, was impressed upon his mind by a case of death from criminal abortion which occurred in his district about a year and a half ago. In this case the

accused was brought to trial and convicted. During the trial dying statements of two different persons were offered in evidence. In one case this evidence, if admitted, would have been favorable to the accused; in the other, to the prosecution.

Dr. March thinks it is important for the physician in attendance upon a woman likely to die from the results of a criminal abortion to have clearly in mind his legal position and responsibilities. He quotes as follows a few of the acknowledged principles which have a bearing upon such cases: Dying declarations are accepted in law without being sworn to. It is naturally presumed that all statements made at such a solemn crisis must be sincere, believed at heart to be true by the dying person, even if subsequently shown not to be so.

The attending physician under such circumstances having expressed the opinion that the patient is dying and in sound mind, a magistrate should be summoned to take down the statements that the dying person may wish to make. Should it not be possible to obtain the services of a magistrate, then the attending physician can take down the dying declarations. The physician should, however, limit himself to writing down the exact words of the dying person, without offering any interpretation whatever. The statements should be read over to the dying person, and, if possible, her signature obtained.

The declarations must be made, not simply *in articulo mortis*, but under the sense of impending death, without expectation or hope of recovery. They are admissible even though others may not have thought the person would die.

The declarations may be signs or other appropriate modes of communication. It is not necessary that the examination of the dying person should be made after the manner of interrogating a witness in the case, although any departure from that mode may affect the value and credibility of the declarations. It is no objection to their admissibility that they were made in answer to leading questions, or were obtained by pressing and urgent solicitation, but the declarations must be made under a sense of impending dissolution. It does not matter that death failed to ensue until a considerable time after such declarations were made.

Declarations of a deceased person are admissible only in reference to those subjects to which she would have been competent to testify if sworn in the case. They must, therefore, in general, speak to facts only and not to mere matter of opinion, and they must be confined to what is relevant to the issue.

The circumstances under which the declarations were made are to be shown to the judge, and it is his province and not that of the jury to determine whether they are admissible.

If the deposition of the deceased has been taken under any of the statutes on that subject, and is inadmissible as such for want of compliance with some of the legal formalities, it seems that it may still be treated as a dying declaration if made *in extremis*.

**Itching and the Itch.**—In a recent number of *La Médecine moderne*, the frequency with which formulæ are published in American medical journals for the relief of pruritus vulvæ is made a subject of comment. The question is asked whether there are peculiarities of race, climate, or environment which tend to make the affection so prevalent among American women that editors have become possessed of the necessity of bringing

the matter forward so frequently in their publications. We do not know how others may account for the fact that pruritus vulvæ receives so much attention at American hands, but our itch editor, to whom we referred the matter, informs us that personally he is a great admirer of French journalism, and constantly flatters French editors in the sincerest way by imitating them. Now, as every one knows who reads the Paris journals, it would be considered an unpardonable oversight for an editor to send out a weekly issue which did not contain the recipe for at least one *pommade contre la gale*.

Having little or no scabies in this country, and much more pruritus scribendi than any other variety, these formulæ are reproduced and made to do service under the faked caption of "pruritus vulvæ."

Now, will our esteemed friend of "modern medicine" enlighten us upon the prevalence in France of *la gale*, to which his own and his contemporaries' journals devote so much attention?—*Medical Record*.

**The Antistreptococcus-Serum Treatment in Rebellious Purulent Streptococcic Dacryocystitis and in other Ocular Streptococcic Infections.**—At a recent meeting of the Société de biologie, a report of which is published in the *Presse médicale* for November 18th, M. Boucheron said that a large number of cases of purulent dacryocystitis were produced by the presence of streptococci, as the recent bacteriological researches of Widmark, Parinaud, and Morax, as well as his own, had proved.

Streptococcic dacryocystitis, he said, appeared to be of frequent occurrence, for streptococci had been found in the majority of the observations published; these, however, were nearly always serious cases.

Purulent streptococcic dacryocystitis was a definite type, characterized by the presence of streptococci in the pus, by the occasionally recurrent phlegmon of the lacrymal sac, by the persistence of suppuration after the acute stage, by the lacrymal conjunctivitis, also frequent, and by the streptococcic rhinitis, which was perhaps still more frequent. Constriction of the nasal canal often preceded and nearly always accompanied suppuration of the sac.

The most rebellious cases were those in which the suppuration of the sac was prolonged after the acute phlegmons in spite of the surgical and antiseptic treatment in use at the present day. In the attenuated forms the suppuration disappeared spontaneously.

For the rebellious cases the antistreptococcus-serum treatment was especially indicated. A hypodermic injection of five cubic centimetres of Marmorek's serum, administered three or four times at intervals of a few days, would cause the subsidence of the suppuration of the lacrymal sac, of the lacrymal conjunctivitis, and of the rhinitis in a short time, without any other treatment.

M. Boucheron cited the case of a woman, thirty-nine years old, who had been troubled with watering of the eyes for four or five years. She had had a primary phlegmon of the sac during pregnancy, as well as three other phlegmons during a period of fourteen months, in spite of the treatment employed. The first hypodermic injection of Marmorek's serum, which had been administered for the persistent suppuration, brought about a considerable amelioration; a second injection two weeks afterward had caused the disappearance of the rest of the pus and of the lacrymal conjunctivitis, and considerably ameliorated the rhinitis. A third injection eight

days later had been made in order to promote these results.

In the local streptococcal infections of the ocular organs, which were capable of producing complications at the time of operations for cataract or other operations, and when there were ocular traumatism, the antistreptococcus-serum treatment might be employed as a preventive. M. Boucheron, in a former communication to the Société de biologie, had related the case of a diabetic patient with cataract, in which he had employed the serum treatment as a preventive, and shortly afterward he had been able to perform an operation without complications resulting. The patient had also presented lymphangitis of the legs.

In the purulent complications which occurred in operations for cataract, of which the streptococcus was often the cause, the serum treatment was indicated if the microscope or the cultures revealed the presence of streptococci.

The conditions for serum treatment were more favorable in local streptococcal infections in which the general condition of the patient was good; in which the dose of serum could be reduced one half, and in which the injections could be given far enough apart to prevent all danger.

**Snake Bite Treated by Antivenene Serum, with Recovery.**—In the *British Medical Journal* for November 21st Surgeon-Major S. J. Rennie, of Meerut, India, relates the following case which, he says, is of interest because it was one of the first cases in which Professor Calmette's antivenene serum was used:

About 6.30 P. M., on September 21st, a Hindu boy, aged eleven years, son of a groom, was drawing water from a well, and in returning accidentally stepped on a snake which bit him on the right foot, the foot being bare at the time. Two men were with him who both saw the snake, but they were unable to kill it before it disappeared in the grass. They promptly bound the end of a pugaree tightly round the boy's leg, and, picking him up, ran with him to the author's quarters. Not more than three minutes had elapsed from the time he was bitten until the author saw him.

The typical imprint of a snake bite, with its two deep fang punctures and the crescentic row of small teeth marks between, was clearly seen on the inner side of the right foot. Mr. Rennie at once injected eight cubic centimetres of Calmette's antivenene serum into the subcutaneous cellular tissue of his abdomen. At the same time Surgeon-Major Birt, A. M. S., treated the wounds and their immediate neighborhood with a hypodermic solution of permanganate of potassium, after which they were carefully washed and dressed. The patient was then placed under observation and seen from time to time during the evening, but he never had a bad symptom, and is now running about as well as ever he was.

There is, no doubt, says the author, one weak point in this case—namely, that the snake was not killed, and that, therefore, there might be an element of doubt as to the nature of its species. The reptile, however, was clearly seen by both men who were with the boy, who gave an accurate description of it, and recognized it as a krait (*Bungarus ceruleus*), that most deadly and dangerous Indian snake. The characteristics also of the wounds were clearly those of a bite from a snake with fangs. Mr. Rennie states that his own personal observation led him at once unhesitatingly to conclude

that the injuries were caused by a poisonous snake, and in this he was borne out by the unanimous opinion of the five medical officers by whom the case was seen, several of them of long and varied experience in India. Taking all these points into consideration, there can, he thinks, be little doubt that the boy was bitten, and bitten savagely and deeply, by a krait, a bite from which, under ordinary circumstances, is necessarily fatal.

**The Treatment of Anal Fissure.**—In the *Journal des praticiens* for November 14th M. Floersheim remarks that the treatment of this disease is above all surgical, although in simple cases medical treatment may be resorted to at first. The number of remedies employed for the cure of anal fissure, he says, is considerable, and their frequent inefficacy has been sufficiently testified to. Among those advocated by different authors, Trousseau and Bretonneau recommend the following enema which is used at the present time:

- R Extract of rhatany..... 90 grains;
- Alcohol, enough to soften it;
- Water..... 4 ounces.

M.

Other preparations which seem to succeed more frequently are the following:

- 1. R Extract of rhatany..... 8 grains;
- Morphine hydrochloride..... 0.3 grain;
- Cacao butter..... 60 grains.

M.

This quantity makes one suppository. Cocaine may be substituted for morphine.

- 2. R Extract of belladonna, } each 75 grains;
- Neutral acetate of lead, }
- Lanolin..... 450 "

M.

The part is to be anointed with this from two to three times a day.

Antipyrine, given in an enema, is sometimes efficient in the following form:

- R Warm water..... 4 ounces;
- Antipyrine..... from 30 to 60 grains;
- The yolk of one egg.

M.

Repeated warm baths or cold enemata may also be used with advantage.

Unfortunately, says M. Floersheim, it is rare to record a definitive success from purely medical treatment; cauterization with silver nitrate, which was recommended by Lenoir, is but a palliative measure which should be rejected because of the pain it gives rise to, so that operative intervention is the only procedure that should be employed to combat anal fissure.

Forced dilatation of the anus, which was established by Récamier, says M. Floersheim, is certainly preferable to all other methods. It is extremely painful, however, and it is necessary to anesthetize the patient with chloroform, or to practise local anesthesia with a fifty-per-cent. solution of cocaine hydrochloride, which is injected around the anus. M. Floersheim states that he has used the latter means and finds that it is sufficient to prevent all pain, provided an interval of five minutes is allowed to elapse before dilatation is practised.

Anal dilatation, continues M. Floersheim, rapidly suppresses pain and spasm of the sphincter, and unfavorable results rarely follow this method; if the operation is not successful, nothing remains but to practise incision, according to Boyer's method, or, better still, excision, cutting with curved scissors around the

fissure and bringing the lips of the wound together with catgut or silk.

**The Action of Chloralose.**—In the December number of the *University Medical Magazine* Dr. James Tyson states that he was induced to make a trial of chloralose after reading a paragraph on its importance as a hypnotic in Dr. George William Balfour's *The Senile Heart*, page 285. At the time, he says, he had under his care a patient with the most obstinate insomnia, for whom he had used ineffectually sulphonal, chloralamide, chloral, trional, and paraldehyde. He ordered for him ten grains of chloralose at bedtime. The effect seemed magical. He went promptly to sleep and slept soundly until morning, awaking much refreshed, and without any of the unpleasant feeling so often consequent on the use of remedies of this class. The dose was repeated the next night and the next with like effect. On the morning of the fourth day the patient informed the author that he had gone through some strange performances in the night; that he had unconsciously removed all his clothing and found himself stark naked in the morning. This experience, says Dr. Tyson, did not impress him seriously, and the dose was repeated the following night. During the night, his wife, who occupied an adjacent room, because of being recently confined, happened to enter his apartment and found him sitting on the edge of the bed, again entirely without clothing. She succeeded in getting him into bed, apparently without arousing him, and he awoke in the morning thoroughly ignorant of what had happened during the night.

A day or two later, continues Dr. Tyson, he was called upon by a friend, the son of a physician, who resided twenty miles out of Philadelphia. The son had just received a telegram from his mother urging him to come at once because of the sudden illness of his father. No particulars were given, but he begged the author to go with him, and in an hour they were at the bedside of the father, a hale, hearty old gentleman of eighty years, who said he never felt better in his life and wanted to know what it was all about. The history of the case was this: The doctor was a confirmed victim of insomnia, and had been for years. He had tried every known remedy for sleeplessness except morphine, and whenever a new one arose some one of his friends was apt to call his attention to it. Thus he had recently learned of chloralose. It had been recommended to him in five-grain doses to be taken in a cachet. He had taken it two nights in succession with the most charming effect, and was delighted with it. The day preceding the next night was stormy and he was not able to take his usual exercise out of doors. In the evening he ate freely of some favorite food; hence he had a little indigestion. At bedtime he took his five-grain cachet of chloralose, but it produced no effect. Twelve o'clock came, but no sleep. He then took half of another cachet, which was also without effect. In two hours he took the remaining half of the cachet. In the morning his wife found him asleep, breathing stertorously, and could not arouse him. She became alarmed and telegraphed for his son. A little later he awoke, feeling very well and thoroughly unconscious of anything unnatural. His wife thought it best, however, to keep him in bed until the physicians arrived.

These cases and others of which Dr. Tyson gives an account were among his earliest experiences with chloralose, which he states he has learned to value high-

ly, for he believes that all the mishaps, which occurred so near together that he could not profit by any one separately, are explainable. First of all, he continues, his first dose was needlessly large, although it was determined by a published statement that thirty-one grains might be given without inconvenience. The dose recommended by those who have made extensive trials with the drug is from a grain and three quarters to fifteen grains, and Haskovec, who has used it largely in cases of insanity, states that the dose should not exceed fifteen grains. Dr. Tyson says that after his own experience with the drug he would under no circumstances advise a dose as large as fifteen grains; on the other hand, a grain and three quarters seems entirely too small for adults. From three to five grains, more generally the latter, he thinks, is nearer the correct dose.

Since the experience related, he has employed chloralose for insomnia a number of times, and believes it to be a valuable drug for that state. Certain precautions must, however, be taken to secure its activity. The most important of these is that it should be given in solution. If it is administered in a cachet or an uncovered powder there are a certain number of chances that it will lie in the stomach for some time undissolved, and therefore fail of its effect, while if the dose is repeated there are more chances that the two doses will act conjointly, and some one or more of the unfavorable effects alluded to succeed. It is most readily soluble in hot water, but may also be taken dissolved in hot milk, and perhaps this last is the best method of administration. It is, however, bitter in solution, and if this quality is objectionable a cachet becomes the next best vehicle.

The class of cases to which it is best adapted is, continues Dr. Tyson, undoubtedly the simple insomnias, since it is not, in any high degree at least, an analgetic. It has been largely used abroad in insane asylums for its effect upon the excitable insane, but he has used it in the insomnia of heart disease and Bright's disease. Its advantages are its promptness of effect when properly administered and the absence of unpleasant results the next day, and especially of the prolongation of the soporose effect into that day, so often incident to hypnotics; there is no headache. Dr. Tyson says that he can not deny, however, that the former effect has occurred, especially in cases of valvular heart disease, where absorption is often slow because of the passive congestion of the stomach. Such effect has been, however, a simple drowsiness.

He adds also that in addition to those met with by himself, other unpleasant effects of the drug have been noted by clinicians, especially when it has been employed in tuberculous consumption. Thus, in the case of a patient to whom Rendu gave a four-grain dose, he was called in two hours to find her "insensible, the pulse 180, the movements of the heart imperceptible, and with epileptoid movements of the limbs. The skin was covered with cold perspiration, and death seemed imminent." She was revived by hypodermic injections of ether, and the convulsions were controlled by a twenty-fifth of a grain of morphine injected hypodermically. She returned to consciousness without any knowledge of what had occurred. Similar results are reported in other cases of tuberculosis from doses of from three to six grains. Such effects from the smaller of these doses seem, says Dr. Tyson, in the light of his experience, surprising. But in this disease, especially where there is great debility, the drug is best avoided. Hysterical

symptoms may be induced by it which must not be mistaken for more serious effects. Quieting effects may be expected in the convulsions of tetanus. In fact, such effects are reported.

**The Wearing of Veils and its Effects upon the Eyesight.**—The *Boston Medical and Surgical Journal* for December 3d publishes an article on this subject, by Dr. Casey A. Wood, in which the author remarks that, although we hear and occasionally read of the ill effects produced by veils upon the eyesight, very little has been done in the way of determining the exact degree of interference with vision which these ornamental and occasionally useful protectors bring about.

The fact that the wearing of veils is productive of weak eyesight, headaches, and sometimes vertigo and nausea is, he says, within the experience of every ophthalmologist. Not only are these effects produced by the eye strain consequent upon the added efforts made by one or both eyes to see through or around an obstruction, but the irregular figuring on the veil itself is, in some instances, a source of annoyance to the wearer. As in other cases of abuse, the author remarks, the burden rests heaviest upon the weakest eyes, and probably the reason why one encounters so comparatively few instances of asthenopia directly due to veil-wearing is that the embarrassed eyes are able to overcome the additional strain where the vision is normal, the oculo-muscular system in proper equilibrium, and the general health good.

Dr. Wood had a dozen typical specimens selected for him for the purpose of demonstrating the extent to which veils of various kinds influenced the eyesight, and made a number of experiments with them, the most important of which he gives an account of, with the following results:

1. Every description of veil affects more or less the ability to see distinctly, both at a distance and near at hand.
2. The most objectionable kind is the dotted veil, although the influence of this variety for evil is more marked in some samples than in others.
3. Other things being equal, in undotted and non-figured veils, vision is interfered with in direct proportion to the number of meshes to the square inch.
4. The texture of the veil plays an important part in the amount and kind of eye strain produced by the veil. When the sides of the mesh are single, compact threads the eye is embarrassed very much less in its effort to distinguish objects than when double threads are employed.
5. The least objectionable veil is that without dots, sprays, or other figures, but with large regular meshes made with single, compact threads.

It is not a necessary consequence of the wearing of veils that eye symptoms should result, continues Dr. Wood, for a healthy eye in a healthy body resists the strain of an impediment to vision just as it does other deleterious agents; and it is only when from other causes the eyesight is weakened that the wearing of an objectionable veil proves immediately and obviously hurtful. Dr. Woods states that he has noted many cases of headache and painful vision, as well as other ocular symptoms, produced by veil-wearing in persons whose eyes are not overstrong; and he believes that this practice is one of the agents, not perhaps always recognized, that contribute to ocular discomfort, and it is not the part of wisdom to compel our visual organs to overcome unnecessary obstacles in the effort to see.

It has been urged in defense of veils, he says, that they are often required for the protection of the face, to keep the hair in order, or to retain the hat in place. If the happiness and comfort of members of the gentler sex are thus bound up in veil-wearing, he adds, they should at least give preference to those veils that do the least harm.

But what excuse can be urged, he asks, for that not uncommon offense, the attempt to read through this unnatural screen? And yet such exhibitions are of every-day and every-night occurrence in places of public resort—street cars, railway trains, churches, theatres, concert halls, club rooms, etc.—thus adding to the injury of defective distant vision the insult of eye strain for near work.

**Veratrum Viride.**—In the *Journal of the American Medical Association* for December 3d Dr. John M. Batten remarks that veratrum viride slows the heart's action and makes it feeble. It was first used by Magendie and Andral in physiological experiments in 1821. Bardsley first used it in rheumatism and dropsy in 1826. The curative effect of veratrum viride lies in its influence on the heart to retard its action in acute inflammatory diseases in which the pulsation is very much accelerated. Dr. Batten states that he has been able to produce the physiological effects of the drug in cases of inflammatory diseases with a dose of Norwood's tincture, not larger than three drops, every three hours. By this dose he has been enabled to reduce the pulse beat twenty or thirty in a minute, especially when the high pulse rate has been caused by inflammation. In inflammatory rheumatism he has had good results with this drug by keeping the pulse at or near the normal until convalescence began. In the early stages of measles, scarlet fever, and in some cases of small-pox, it acts favorably in governing the heart's action. In typhoid fever where the heart's action is irregular, he has thought that this drug in drop doses aided in steadying it. For this purpose he has, in the treatment of typhoid fever, continued the use of the drug in drop doses until convalescence set in. In all acute inflammatory diseases of the chest it is an excellent remedy; in acute pneumonia, pleuropneumonia, and pleurisy. If in acute pneumonia the pulse can be kept at or near the normal by this drug in the stage of congestion, the author states that we may often be able to jugulate it or prevent it from entering upon the hepatization stage. Even in a sthenic case in the second stage veratrum viride acts well. The heart's action is lessened without loss of blood as in venesection.

Dr. Batten refers to a paper entitled *Should we Bleed or not Bleed in Acute Pneumonia?* which was read by a gentleman before the American Medical Association in 1893. In the discussion of the paper, he says, opinions were diverse. One gentleman advocated veratrum viride in the treatment of acute pneumonia. He had such entire confidence in the treatment of the disease with this drug by keeping the pulse at or near the normal, that he made the bold assertion that all cases could be cut short by this mode of treatment.

Dr. Batten gives the histories of two cases, in the second of which the patient had an attack of heart failure caused by the cumulative effect of the veratrum viride, and he states that it is his opinion that the failure of the heart acted favorably on the course of the disease, as the turning point seemed to be established at this time. In each of the cases he enveloped the chest in an oil-silk jacket.

## Lectures and Addresses.

### LECTURES ON ANGINA PECTORIS AND ALLIED STATES.

By WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

#### LECTURE VII.—DIAGNOSIS, PROGNOSIS, AND TREATMENT OF ANGINA PECTORIS.

(Concluded from page 768.)

**TREATMENT.**—"The first and great object of the practitioner on being called on to treat a case of angina will be to make himself acquainted with its individual character. Beginning with the early history of the disease, he will trace it to its present stage, and will endeavor, from the narrative of the patient and from the observation of the whole phenomena presented to him, to form a clear judgment respecting the local condition of the organs in which the characteristic symptoms have their site, and the state of all the other parts of the system which can in any way influence these; in other words, he must endeavor to ascertain the species or variety of angina, according to the distinction formerly pointed out." This clear statement of Sir John Forbes forms a fitting introduction to the discussion of this part of our subject. Successful treatment depends often upon correct diagnosis; but there are cases of angina pectoris brought to the consultant in which diagnosis and prognosis in themselves constitute the treatment. To a man who has felt that judgment has been given against him, the doom pronounced, and whose mind is haunted with the dread of sudden death, the assurance that the condition is functional and curable comes as a reprieve, and may be the one thing necessary to effect a cure.

**True Angina.**—Determine in the first place, if possible, the existence of any constitutional disease, as syphilis, gout, or diabetes, and the presence or absence of valvular lesions.

(a) **General Management.**—Inquire carefully about the exciting causes of the attacks, which differ in different cases. Usually the patient has learned by bitter experience his limitations in certain directions, and knows much better than you can tell him just what to avoid; but you can emphasize the importance of mental worry, exercise, and diet, the three chief factors. Quiet of mind, avoidance of worries and cares, the cultivation of a calm equanimity—with these, or such like phrases, we try to impress a poor victim who to previous anxieties has now the added burden of a disease the terrible character of which he can appreciate but can not understand. Our words often seem a mockery, and yet they may be helpful in persuading a man to cast off all unnecessary business and to live a life in which there shall be a minimum of friction. Time, too, with its

soothing deception, comes to allay the access of early apprehension, and as succeeding attacks pass there may be less and less mental distress. An important question arises here, Shall a man with angina give up his business? In a majority of cases this sacrifice is unnecessary; the literature abounds with examples of men who, like John Hunter, have done the best work of their lives after the onset of angina. There is so much uncertainty that no rule can be laid down; each individual case must be considered separately. The patient's age, occupation, and, above all, the condition of the vascular system, must be taken into account. Even after a most severe attack, followed by a cardiac breakdown of several months' duration, a man may be able to resume work, and, as in Case V, referred to in Lecture III, be benefited by the steady occupation.

**Exercise** must be taken within the limits which each individual soon learns to recognize. In severe recurring attacks induced by slight muscular efforts, a period of absolute rest should be enjoined. The sudden, quick movements which rapidly increase the blood pressure and throw a strain upon the heart are the most dangerous; and most of all those with which are associated strong emotions. The patient should be urged to walk on the level, in the literal as well as metaphorical meaning of the phrase. He should learn "to live within the income of his circulation," with which wise saw from the lips of the late Dr. Sibson a friend with organic heart disease has been comforted and sustained for a quarter of a century. Steady, quiet exercise should be encouraged, except, of course, when there are special signs of cardiac weakness, in which case the resistance gymnastics of the Schott method may be tried.

**Diet** is in many cases the central point in the treatment. The subjects of angina are often men with large appetites, accustomed to eat freely of rich and strong foods. First, limit the amount taken, which in most persons above forty years of age is far too great; second, see that the quality is suitable by excluding from the dietary rich, highly seasoned foods and those which favor fermentation; and third, arrange the hours for eating. The subjects of angina are usually aware of the necessity of limiting the quantity of food and drink taken at one time. So soon as the stomach is distended there may be warnings of distress about the heart, or in aggravated cases a full meal may always cause an attack. As one patient expressed it, "Had I not to eat, I would never suffer." Light meals should be the rule in all cases; at breakfast and at midday dinner more may be taken than at the evening meal. Late suppers should be interdicted—there is "death in the pot" for angina victims, and a surfeit may be as fatal as poison.

The quality of the food is equally important. Special dietaries may be necessary for patients with gout and glycosuria, but in ordinary cases the food is to be regulated with reference to one all-important feature—

viz., flatulence. As you may remember, almost every one of the old writers laid the greatest stress upon this element in the causation of the attacks, and they were right. In dealing with the question of diet we are too apt to adopt some fad to which, with Procrustean precision, we fit every case. A more rational way is to recognize the extraordinary peptic diversity in our patients—in no respect more strikingly shown than in this very matter of flatulency. Beyond the generally accepted restriction of the carbohydrates we can not go very far without meeting individual peculiarities which have to be considered. The patient himself has to be consulted carefully. Some of you may call to mind what our distinguished colleague Dr. Smollett makes one of his characters, Matt. Bramble, say in *Humphrey Clinker*: "For my own part, I have had a hospital these fourteen years within myself, and studied my own case with the most painful attention, consequently may be supposed to know something of the matter." We are too apt to forget this. An intelligent man should be able to tell you just what articles of food cause most disturbance and produce wind in the stomach or bowels. The fault may not lie in the food, but in the inability of the stomach and bowels to digest it properly. The obese, flabby subjects of angina—not the most numerous class in my experience—and those with weak heart and arteriosclerosis are specially prone to flatulence. A few doses of blue mass, an occasional saline purge, and the use at times of a good bitter tonic keep this condition in check. The use of hot water before meals, particularly before breakfast, has been found very serviceable.

In elderly men accustomed to stimulants, hot grog at bedtime allays the tendency to flatulency, which is sometimes the cause of wakefulness, or which is apt to disturb the patient in the early morning hours. Peppermint, spirits of camphor, Hoffman's anodyne, carbolic acid, iodine, and creosote are useful for "wind on the stomach." For the intestinal flatulency a saline purge is often a good corrective; the various supposed intestinal disinfectants may be tried—salol, beta-naphthol, and corrosive sublimate, of which pilules of from one sixtieth to one thirtieth of a grain may be given sometimes with advantage.

(b) *General Medical Treatment.*—Of constitutional conditions underlying angina pectoris and capable of treatment, syphilis and gout are the most important. Genuine angina in a man under thirty-five years of age should arouse a suspicion of syphilis, and vigorous measures should be adopted. In gouty cases free elimination by the bowels, skin, and kidneys should be secured, a proper diet ordered, and at intervals a course of colchicum may be prescribed.

One patient, Dr. —, emphasized repeatedly the benefit he had derived from colchicum. Stimulants should be avoided. Glycosuria is usually controlled by diet, and rarely gives much trouble.

In a large proportion of all cases of angina pectoris the treatment consists in the administration of the iodides and nitrites, remedies which are believed to influence arterial function and arterial nutrition. The use of the iodides of potassium and sodium in this disorder has been advocated most warmly by Huchard, who states that of eighty patients with organic angina treated thoroughly by these drugs twenty-two recovered, forty-three were greatly benefited, and fifteen died.\* The iodides appear to have a beneficial effect in checking or modifying the progress of arteriosclerosis and in lowering the blood pressure. They may influence, too, arterial pain. I have called your attention repeatedly to the influence of iodide of potassium in aneurysm of the aorta, in which the relief of the pain is one of its most striking effects. While I can not say that my experience is in every way so favorable as Huchard's, I can testify to the great relief which has followed its use in many cases, and in a few an apparent cure. Cases which were thoroughly treated nearly ten years ago remain quite well, and I have had within the past three years several patients who have been greatly benefited. I usually order the iodide of potassium in doses of ten or fifteen grains three times a day. Should it disagree, which is very seldom, I give the sodium salt. Larger doses are not often necessary. If intolerance develops, stop the use for a week and begin with smaller doses. The success in treatment depends upon the perseverance with which the drug is used. On this point let me quote from Huchard's pamphlet: "One of the principal conditions of success is perseverance—constancy in the medication. The drug must be taken for a period of two to four years, in daily doses of one to three grammes, until all symptoms of angina have disappeared for many months, and I hold that a permanent and definitive recovery is not obtainable except after many years of treatment." Reasonable caution must be employed, and you would not give the iodides in patients with advanced arterial degeneration, a dilated heart, and signs of interstitial nephritis. The patients who stand the treatment well are the robust, middle-aged men in whom the angina is the sole symptom. With aortic disease, if fairly compensated, the drug may be used.

The nitrites in hypertension and angina pectoris are of value quite equal to the iodides. The nitrite of amyl is employed in the paroxysm. The nitroglycerin or trinitrin is indicated in all cases in which the tension is persistently high. Given properly, it is a very valuable remedy, but to get any advantage from its use each case must be taken by itself. In the first place, be sure that the nitroglycerin, either in solution or tablets, is fresh. The tablets containing one one-hundredth of a grain are, as a rule, reliable. It is well to begin with only one of these three times a day. The dose may be increased gradually until the patient takes four or five three times

\* *Le Traitement de l'angine de poitrine*, Paris, 1892.

a day, or even a larger dose. If the patient notices a slight glow or flush and a little sensation of fullness in the head you may know that the remedy is acting. I feel sure that in individual cases we often do not employ the drug in sufficient doses. I have never seen it do any harm. The extreme flushing and throbbing headache give reliable indications when the limit has been reached. I have given as much as thirty minims of the one-per-cent. solution, three times a day, to a case of chronic arteriosclerosis, without any disturbance. The nitrite of sodium, recommended by Hay, may also be tried in doses of five to ten grains three times a day.

Among other remedies which are useful in the general medical treatment of angina, arsenic is sometimes very valuable. Balfour advises it particularly in the weak heart of elderly people, when associated with pain of any kind. In cases of feeble heart with anæmia, iron and strychnine are most valuable remedies, and in order not to trouble the patient with too many doses, arsenic, iron, and strychnine may be given together in compressed powder or pills.

(c) *Treatment of the Attack.*—So frequently is the paroxysm excited by gastro-intestinal disturbances that the subjects of angina should not only be warned to be on their guard in this matter, but should be prepared to take prompt measures on the first indication of any distress. No doubt it was from this standpoint that W. W. Ord made the somewhat paradoxical remark that if restricted to the use of one drug in angina he would prefer sulphate of magnesium to nitrite of amyl. A patient should be told to use a saline purge or blue mass or small doses of calomel when he feels gastro-intestinal uneasiness. It frequently happens that much more prompt treatment is necessary for a condition of flatulency. He should be provided with Hoffmann's anodyne and spirits of camphor; a teaspoonful of each in some peppermint water or hot whisky makes an excellent carminative draught. The combination of morphine, cannabis indica, hyoscyamus, capsicum, peppermint, and spirits of chloroform which is now prepared either in liquid or tablet form as chlorodyne is sometimes very advantageous. In tablet form it is particularly convenient, as it may be carried in the waistcoat pocket.

For the paroxysm itself there are three remedies:

Nitrite of amyl, two to five minims, inhaled from a handkerchief, or from cotton wool placed at the bottom of a wineglass, gives prompt relief in certain cases. The patients are in the habit of carrying the remedy in *perles* containing three to five minims, which can be rapidly broken in a handkerchief and inhaled so soon as the very earliest symptoms of the attack are noticed. The introduction of this drug, in the treatment of angina, by Dr. Lauder Brunton has certainly been a great boon to many sufferers, but too much must not be expected of it. It is singularly uncertain. While in one case the attacks are promptly cut short and almost immediate re-

lief obtained, in others it seems quite inert. Curiously enough, considering that its physiological effect is in dilating the peripheral vessels and relieving the widespread angiospasm, in my experience it has been less efficacious in the vasomotor type of the disease than in cases of organic angina. It may produce its effect with great rapidity, as shown by the flushed face of the patient and the increased volume and softness of the pulse, without relieving the pain. It sometimes acts better, given by the mouth, combined with the tincture of capsicum in peppermint water.

Morphine hypodermically is the most useful drug in the attack, and if the pain is not relieved quickly by the nitrite of amyl an injection of a quarter of a grain should be given, and repeated in a half or three quarters of an hour if the patient is not relieved. In one case the nitrite of amyl failed repeatedly to give the slightest relief, but from a quarter to a third of a grain of morphine, hypodermically, never failed to allay the terrible distress, and seemed also to steady and improve the heart's action. A point about the use of morphine in angina which I have never seen mentioned except in the paper by Dr. Burney Yeo in the *Practitioner*, already referred to, is the remarkable tolerance of morphine in certain cases. In reporting Case XXXII I mentioned that this patient received between ten o'clock on Saturday night and 1 P. M. on Sunday five grains of morphine hypodermically and by the mouth, which relieved the pain but did not give him sleep. There are cases in which a hypodermic injection of a quarter of a grain of morphine given at the first indication of the attack, as a numbness in the hand or tingling in the fingers, checks it at once.

And third, in any paroxysm of great intensity, while waiting for the nitrite of amyl or morphine to take effect, chloroform may be dropped upon a handkerchief and inhaled. Balfour recommends that it be poured on a sponge in a smelling bottle, and the patient told to breathe it through the nose as deeply as possible. In a minute or two relief is obtained, and as the patient comes under the influence of the drug the bottle drops from his hand, and there is in this way no danger of an overdose. The chloroform acts much more promptly and is much pleasanter to take than ether, and I have never seen any dangerous effects from its use, even in persons with very weak heart's action.

(d) *Treatment of the Complications.*—For the syncope of serious attacks the aromatic spirits of ammonia with Hoffmann's anodyne and brandy may be given, or hypodermic injections of ether or camphor. For the dilatation of the heart and cardiac weakness, which sometimes follow the attack, the nitroglycerin with strong frictions to the limbs may favor the circulation at the periphery, while digitalis or digitalin may be given freely to stimulate the heart's action. Digitalin sometimes acts well, as in Case XXXVIII, and may be given hypodermically. No hard-and-fast rule can be laid

down regarding the use of digitalis. It sometimes acts badly, as in a case very carefully studied by W. T. Sharpless, of West Chester. Caffeine and camphor may also be employed. If all these measures seem futile, I would not hesitate to employ puncture of the heart—cardioecentesis—which may arouse to quite vigorous action a dilated and parietic organ. I do not know that this has been employed in the cardiac asystole following a severe paroxysm of angina, but there are instances on record, notably the case of Sloane (*Edinburgh Medical Journal*, vol. xl), in which puncture of the heart with a needle driven firmly into the ventricle has aroused the flagging action without apparently doing the slightest injury.

For the condition of chronic *état de mal angineux*, in which, for a period of many days or even weeks, the patient has recurring attacks with cardiac asthma and feebleness of the circulation, your resources will be taxed to the uttermost. For the dyspnea and the Cheyne-Stokes breathing full doses of strychnine, hypodermically, may be employed, from a fortieth to a twentieth of a grain, three or four times a day. Special care should be taken that the bowels are kept freely opened. The cardiac measures already spoken of may be employed, and flying blisters to the præcordia and to the bases of the lungs may sometimes give relief.

*Treatment of Pseudo-angina Pectoris.*—The measures must usually be directed to combating the underlying condition of neurasthenia or hysteria. Occasionally it happens, particularly in medical men, that the mental relief afforded by a positive diagnosis of pseudo-angina is in itself sufficient to effect a cure. Cases II and III, given in Lecture V, are good illustrations of the improvement and permanent cure, up to the present date, of attacks of maximum severity. It is not easy to say to what the rapid relief could be attributed, as the patients were given only general tonics. In other cases the attacks recur for years, as in the wife of the physician from the Province of Quebec, of whom I spoke, who had had attacks for twenty-five or thirty years. In the severe form, particularly when associated with much vasomotor disturbance, the Weir Mitchell treatment may be tried with advantage. The effects of seclusion, systematic massage, and electricity, particularly the static form, are sometimes most satisfactory. Where this is not feasible hydrotherapy should be tried, either a systematic course at some institution, or, if this is not practicable, the systematic use of the wet pack at night, followed by thorough friction, will be found advantageous. Some of these cases, particularly if treated at the patient's home, tax to the uttermost the resources of the physician. The change of air and scene in traveling will often be found of advantage.

Drugs are of uncertain and doubtful benefit. We often have to order the bromides and valerian, and in cases with much cardiac irritability and vasomotor disturbance the use of nitroglycerin in large doses seems sometimes to aid in equalizing and steadying the circula-

tion. In looking over the notes of my cases of pseudo-angina I notice this hopeful feature; that with but one or two exceptions the patients are at present not only alive and well, but free from attacks.

When the attacks of angina are due to the abuse of tobacco, the patient should give up the habit entirely. I do not think there is much risk, either, in stopping abruptly. Counter-irritation over the heart by means of the Paquelin cautery or blisters, the use of strychnine in full doses, and, if the pulse tension is high, that of nitroglycerin, are measures which will be found efficacious.

In the worry and strain of modern life arterial degeneration is not only very common, but develops often at a relatively early age. For this I believe that the high pressure at which men live, and the habit of working the machine to its maximum capacity, are responsible, rather than excesses in eating and drinking, or than any special prevalence of syphilis. Angiosclerosis, creeping on slowly but surely, "with no pace perceived," is the Nemesis through which Nature exacts retributive justice for the transgression of her laws—coming to one as an apoplexy, to another as an early Bright's disease, to a third as an aneurysm, and to a fourth as angina pectoris, too often slitting "the thin spun life" in the fifth decade, at the very time when success seems assured. Nowhere do we see such an element of tragic sadness as in many of these cases. A man who has early risen and late taken rest, who has eaten the bread of carefulness, striving for success in commercial, professional, or political life, after twenty-five or thirty years of incessant toil reaches the point where he can say, perhaps with just satisfaction, "Soul, thou hast much goods laid up for many years: take thine ease," all unconscious that the fell sergeant has already issued the warrant. How true to life is Hawthorne in the *House of the Seven Gables*! To Judge Pyncheon, who had experienced a mere dimness of sight and a throbbing at the heart—nothing more—and in whose grasp was the meed for which he had "fought and toiled and climbed and crept"; to him, as he sat in the old oaken chair of his grandfathers, thinking of the crowning success of his life, so near at hand, the avenger came through the arteries.

"With what strife and pains we come into the world we know not, but it is commonly no easy matter to get out of it," Sir Thomas Browne says; and, having regard to the uncertainties of the last stage of all, the average man will be of Cæsar's opinion, who, when questioned at his last dinner party as to the most preferable mode of death, replied—"That which is the most sudden." Against this, one in a string of grievous calamities, we pray in the Litany, though De Quincey insists that the meaning here is "unprepared." In this sense sudden death is rare in angina pectoris, since the end comes but seldom in the first paroxysm. Terrible

as are some of these incidental conditions accompanying coronary artery lesions, there is a sort of kindly compensation, as in no other local disease do we so often see the ideal death—death like birth, “a sleep and a forgetting.”

### UTILITY AND RECENT DEVELOPMENTS IN CENTRIFUGAL METHODS.

By C. W. PURDY, M.D.,  
CHICAGO.

ALTHOUGH the centrifuge has been in use for medical and allied scientific purposes for a number of years, yet its real value can scarcely be said to be fully appreciated by the medical profession at large, if we are permitted to judge of its appreciation by the extent of its present use and the scarcity of literature thus far devoted to its consideration. Notwithstanding its apparent lack of general appreciation at present, the proper utilization of centrifugal force must soon develop a principle destined to revolutionize certain quantitative chemic methods: the investigation of organic fluids, including the detection in the latter of micro-organisms with certainty and almost unerring precision, and the estimation of the different actual and proportional elements of the blood; and all with a rapidity that would seem incredible in any other than the present age. In order, however, to cover such a wide and immensely important field in the realm of medical science, greater perfection is demanded of our apparatus than that which we have hitherto possessed, since for the most part the centrifugals in use to date are chiefly efficient in dealing with the coarser sediments, and therefore their range of utility is confined to a comparatively limited field of usefulness.

For ordinary examinations of the urine and organic fluids for the coarser sediments, as cellular elements, casts, crystals, etc., the centrifugal should possess an arm of such length that there should be at least twelve inches from tip to tip of the sediment tubes; and the motor should be capable of a sustained speed of twelve to fifteen hundred revolutions a minute, which will exert a centrifugal force of from twelve to fifteen hundred times greater than that of gravitation. Very few, if any, of the motors in the market meet the above-described requirements. The rate of required speed is often attained and indeed exceeded, but in the requisite length of arm they nearly all fail; or, if the latter be attained, the requisite rate of speed is lacking.

The uses and advantages of the centrifugal in dealing with the coarser sediments, as compared with the older method by gravitation, will appear more striking in the way of contrast by first pointing out the many

disadvantages of the latter. The most serious drawback with the old method by gravitation was the necessary and inevitable delay, since sedimentation could only be secured after many hours' standing. This objection alone would long since have proved fatal to the employment of gravitation as a method of sedimentation in practical work had more rapid means been available for the purpose, because delay entailed a host of vital objections in practical clinical work, some of the more prominent of which are as follows: (a) Delay in diagnosis, often at the expense of the patient's life. (b) Chemic alterations, both in the sediment and medium, which often so altered the morphological features of the sediment as to render it unrecognizable; or the development in the medium of micro-organisms in such abundance as to obscure the microscopic field from definition of its contents. (c) In the case of crystalline deposits in the urine, delay is fatal to diagnostic purposes, since it is only by examination of urine when freshly voided, before crystals form, which are deposited from all normal urines upon long standing, that a distinction between normal and pathological crystalline deposits is possible.

The second serious drawback with the old method of gravitation was its inefficiency. Either in consequence of reduced consistence of the medium, as in highly albuminous urine, or the relatively light atomic weight of the sediment, as in the case of hyaline casts, one could never be certain in diagnostication, because negative results did not necessarily prove absence of the bodies sought for, since, for the reasons just stated, they may have failed to settle though subjected to the force of gravitation for twenty-four or more hours.

Now, a properly constructed centrifuge, capable of a speed of twelve to fifteen hundred revolutions per minute, effectually does away with all the above-considered and many other objections to the old method. The immense impetus exerted upon the sediment by a centrifugal force nearly two thousand times greater than gravitation causes prompt precipitation of morphological elements, almost regardless of their atomic weight or the consistence of the media in which they may be present. It is true, the writer has met with a few observers of unquestionable standing and experience who after trials with the centrifugal—more especially in urinary work—have preferred the old method by gravitation; but for the most part, upon investigation, the fact became revealed that they had been working with inferior centrifugals which by no means complied with the essentials just laid down for efficient machines.

By the aid of properly constructed centrifugals microscopic diagnosis of coarser sediments assumes the desirable features of rapidity and almost absolute certainty. Cases of obscure nephritis (interstitial) with impending uræmia may therewith be unmasked on the spot—often in time to avert a fatal result. Operative

surgery in many cases need only pause for five minutes until aspiration and the centrifuge permit the microscope to point to the nature of the pathological process necessitating operation, when the latter may proceed upon definite and exact lines of diagnosis to more certain success. An exact and unaltered picture of a given pathologic process as represented in the resultant sediment may be presented to the clinician with the utmost rapidity and freedom from changes contingent upon delay. In short, for all purposes of microscopic examinations of fluid media, centrifugal sedimentation by means of properly constructed centrifugals without doubt vastly outranks the older method by gravitation.

In addition to the above-named advantages, recently there has been perfected a method of quantitative bulk measurement by percentage of precipitates which can be compassed with rapidity and accuracy exceeding the ordinary approximate methods in use for clinical purposes. Valuable as all these advantages unquestionably are in practical clinical work, yet the centrifuge can not be said to have compassed its larger field of usefulness until it has included within its range practical and efficient methods for the detection and isolation of micro-organisms. That in the inclusion of this field the centrifugal is capable of development into one of the most essential of all the instruments in the bacteriological laboratory, second indeed only to the microscope itself, seems self-evident. In order to extend the range of usefulness of the centrifugal to include the field of bacteriological research in fluid media, it only requires refinement of the principle upon which the apparatus is constructed, somewhat greater perfection in detail of construction of the apparatus itself, and special appliances for concentration and manipulation of the sediment within more limited areas.

In dealing with the finer sediments, such as micro-organisms, we have to do with objects so minute as often to tax the highest powers of the microscope to recognize them; and, furthermore, they are often present in sparse numbers scattered through bulky media. It is therefore evident that certain conditions must be complied with in order to render search for micro-organisms successful with sufficient uniformity and certainty to be available for practical clinical work. The two chief essentials of the centrifugal for success in this field are (a) very high rates of speed of the motor, and (b) special appliances for concentration and fine manipulation of the sediment. It is to be greatly regretted that centrifugals have been highly recommended for purposes of bacterial search which have in no way possessed the above-described requirements. Such facts have only served to bring the centrifuge into disrepute in the very field wherein it is capable of becoming of the very greatest scientific and practical value. We often hear, for instance, of successful search for the *Bacillus tuberculosis* in the urine by the aid of centrifugals of the speed of which does not exceed a thousand or twelve hun-

dred revolutions, with relatively short arm for sedimenting tubes, and with no special provision for concentration of the sediment other than the old blunt-tipped sediment tubes. It is true that search may occasionally prove successful with such apparatus, for even moderate speed will cause precipitation of the relatively heavy pus sediments, and patient search of this pus, if from tuberculous lesions, may lead to the discovery of the micro-organisms sought for. Much time, however, is unnecessarily wasted by such roundabout methods, but they entail altogether too much uncertainty, and will, therefore, for the most part prove disappointing in practical work.

While the atomic weight of micro-organisms in general is proportionately greater than that of the fluids in which they are found, yet these fluids are often thick, viscid, and more or less resistant to precipitation of micro-organisms unless propelled by forces many thousands of times greater than gravitation, and even then special treatment of the medium is often essential for success, as with sputum, or with the urine in cases of cystitis. The range of speed required of the centrifugal to render it successful in sedimenting micro-organisms in practical work should be not less than five thousand revolutions per minute, and the arm should describe a circle the diameter of which is at least eight inches. If such a motor is supplied with proper appliances for concentration and fine manipulation of the sediment, it will give satisfactory results in practical work, and the higher the rate of speed above the range just indicated, other conditions being equal, the more efficient will be the apparatus in this special field of work.

In determining the percentage and relative proportions of the red and white blood-corpuscles by means of the hæmatocrite attachment, very high rates of speed are also demanded of the motor—at least five thousand revolutions a minute. At such speed the red corpuscles are all packed firmly at the distal ends of the hæmatocrite tubes in a column that does not materially change after two or three minutes, by further operation of the motor; and the same is true of the white corpuscles, which, in consequence of their lighter weight, occupy a second and distinct column above the red corpuscles. Micro-organisms in the blood may also be isolated and examined by the aid of the hæmatocrite tubes, and this demands still higher rates of speed for satisfactory work.

Having reviewed the range of utility as well as the possibilities of the centrifuge and the chief requirements for each special field of work, it may now be useful to glance at our present resources for meeting these requirements. Up to the present time, no successful attempt has yet been made, with a single exception to be considered later, of combining all the requirements in one apparatus. The very excellent apparatus designed by Dr. Daland, of Philadelphia, is adapted for the special use of the hæmatocrite and is fitted with

tubes for sputum examinations. This centrifugal is capable of very high rates of speed, and for the purposes for which it was designed it answers the requirements very well. A large number of hand-power centrifugals are to be found in the market; indeed, almost every prominent instrument house furnishes some such specialty. Some of these are capable of very fair rates of speed, but most of them are fitted with short arms which neutralize the power otherwise attainable by their increased speed. With few exceptions the price at which most of these centrifugals are furnished precludes the excellence of workmanship in their construction that is absolutely essential for refined work. In addition to these, centrifugals have been constructed with motors adapted for water power, the speed of which varies according to the pressure available, but thus far they have not proved satisfactory, in practical use, chiefly on account of the comparatively low rate of speed obtainable.

To Thomas Stenbeck is due the credit of producing the first electric centrifuge, although the writer was engaged in the construction of his electric centrifugal when Stenbeck's apparatus first appeared. The employment of electricity as a centrifugal motor power marks a distinct advance in the efficiency of the centrifugal for medical uses, for the following reasons: (a) It does away with hand power and renders work more easy and convenient; (b) it greatly economizes time, as the operator can go on with collateral work while precipitation of sediments is in progress; (c) it furnishes a power that can be accurately gauged, thus producing speeds of sufficient uniformity to render them available for quantitative determinations of sediments. It would seem that Stenbeck had in view only the first two of

shown in the cut (Fig. 1), is a twelve-volt motor with the arm so constructed that the sediment tubes describe a circle the diameter of which is fifteen inches; and it attains a sustained speed of six to eight hundred revolutions a minute, and the sediment tubes possess a capacity of fifteen cubic centimetres each. The sediment tubes are twelve centimetres in length and sixteen millimetres in diameter, and have a slight constriction or neck beginning at one centimetre from the tip and extending a centimetre and a half up the tube. There is no special arrangement for concentration of the sediment other than the neck of the sediment tube, and this only serves to cause currents in the fluid which often dislodge the sediment, especially when small in quantity, when the motor comes to a stop. This centrifuge is not capable of sedimenting micro-organisms in practical work, as was alleged for it, because it is incapable of sufficient speed, and even if it were capable of the latter it is not sufficiently strong to withstand high rates of speed. The arm of the Stenbeck centrifuge is only three millimetres in diameter—about as heavy as an ordinary knitting needle—while the sediment tubes are without guards, although they swing upon pivots no larger than ordinary pins. It will therefore be readily seen that strength and durability are features almost completely ignored in the design and construction of this centrifugal.

FIG. 1.—Stenbeck's electric centrifugal.

these advantages, since he failed to make any application of the third and last. Stenbeck's electric centrifuge,

FIG. 2.—The Purdy electric centrifuge.

FIG. 3.

Profiting by the defects in the Stenbeck apparatus, after several months' experience in its use, the writer was enabled at length to greatly improve his original model and present to the profession his electric centrifuge in a highly perfected form. This centrifugal consists of a fifty-two-volt motor, the armature of which is laminated and so wound as to enable it to be operated by either direct or alternating currents, and by means of a proper resistor of about three amperes the voltage may be increased to one hundred and twenty. This

range (fifty-two to one hundred and twenty volts), it will be observed, includes the whole field in present use of incandescent illuminating currents employed for lighting buildings. This centrifugal was designed with special regard to strength and durability as well as perfect safety at the highest rates of speed—all the glass tubing being provided with metallic guards, and the arm is constructed of heavy brass metal.

The glass sediment tubes were especially designed to overcome the disadvantages of the old blunt-end and bulb-tip tubes formerly in almost universal use—exact experimentation having proved that tubes the calibres of which were from six to seven millimetres in diameter always retained precipitated sediments, however small the quantity; indeed, with such tips the sediment tubes may even be inverted without dislodging the sediment, which latter is held firmly in position by capillary force. According to the results of these experiments, the sediment tubes for this apparatus were drawn out at the tips to the length of twenty millimetres at diameters of six millimetres and a half, which served to concentrate as well as to retain the sediment. The capacity of these tubes is fifteen cubic centimetres each, and consequently a pair of them carry an ounce of fluid. Percentage determinations of sediments may be made with most rapid and excellent approximate results by the aid of the percentage tubes designed for this centrifugal which are shown in the cut, Fig. 3. These tubes have the same form and capacity as the sediment tubes already described, but are graduated to ten cubic centimetres in tenths of a cubic centimetre; hence each tenth of a cubic centimetre as marked on the scale represents just one per cent. bulk measurement. Above the ten-cubic-centimetre mark the percentage tube possesses a capacity of five cubic centimetres for reception of the chemical reagents employed in precipitating the substance desired to be measured.

In order to secure uniformity of results in determining the bulk percentage of precipitates, a uniform rate of speed and a standard length of time are absolutely necessary in operating the motor. This standard has been fixed at one thousand revolutions a minute, and the time at three minutes. This standard has been found to obtain very uniform and satisfactory results with precipitates mostly sought for in the urine and fluids of similar consistence. Rarely, as in the case of albumin, more especially when the percentage thereof is very high, greater speed and even longer time may be necessary to cause all the albumin to pack firmly so that there shall be no subsequent change in the reading of its column on the scale. In such cases it is advised to use such speed and time as are found sufficient to effect the purpose—i. e., until the column of albumin does not materially alter by further operation of the motor.

With regard to the practical efficiency of this method

of percentage determination, by way of illustration the writer would mention the fact that he has for nearly three years discarded the Esbach method, so long in use for determining albumin in his laboratory, as well as the ordinary quantitative methods for chlorides, phosphates, and sulphates of the urine, effecting the most satisfactory practical estimations of all four of these substances by means of a double arm with his electric centrifuge within five minutes' time.

At the request of the writer, Messrs. Williams, Brown, & Earle \* have recently added a special arm to this centrifuge for the use of the hæmatocrite and for small sediment tubes especially designed for bacteriological work. This arm, shown in the cut (Fig. 4), it

FIG. 4.—Special arm for hæmatocrite and tubes for sedimenting micro-organisms.

will be observed, is a modification of the ordinary arm in use for carrying the hæmatocrite tube. The greatly diminished size of this arm, compared with that in use with the larger sediment tubes of this motor, so greatly diminishes the resistance of the motor when in operation that the speed can be readily increased to the enormous rate of over ten thousand revolutions a minute, or a linear speed of five hundred and thirty-two feet a second. Such a speed exerts a centrifugal precipitating force upon sediments about eight thousand five hundred times greater than that of gravitation. In working with a comparatively bulky medium, such as the urine, where the micro-organisms sought for are comparatively few, as is often the case with tubercle bacilli, two large sediment tubes (holding an ounce) may be filled with the suspected urine and revolved until the sediment is packed in the points of the tubes within an area of, say, two cubic centimetres. The larger arm of the centrifugal may then be removed from the motor and the smaller one adjusted in its place. By means of an ordinary nipple pipette the sediment may next be transferred from the points of the large tubes to the smaller ones, and the latter adjusted in the hæmatocrite arm, when the motor can be operated at its highest speed. By this means it will be observed that the highest precipitating power of the motor is practically brought to bear upon the sediment of a whole ounce of urine within a very limited area. The more minute the sediment the greater the concentration resulting in the conical tips of the tubes. With the motor operating at a speed of ten thousand revolutions, the concentration of the sediment in two or three minutes attains almost a state of solidity. The degree of practical utility of

\* The Purdy electric centrifuge, with all accessories, is now manufactured exclusively by Williams, Brown, & Earle, 33 and 35 South Tenth Street, Philadelphia.

this method of search is best illustrated by the fact that by subjecting an ounce of fluid (such as the urine) to the centrifugal in the above-described manner, from seventy to eighty per cent. of the micro-organisms present will be found in the first two millimetres of the distal ends of the small tubes—an area of rather less than two minims. By next removing the tubes from the small arm of the motor the sediment may be manipulated with the greatest possible accuracy as well as simplicity. The tubes being fitted with movable corks at the large ends, a little pressure upon the cork will cause the sediment at its most concentrated location to appear at the points of the tubes in small- or large-sized drops as may be required, when it may be deposited upon a glass slide without possibility of waste, and it may then be examined under the microscope.\* In conclusion, then, it will be seen that the design of the Purdy centrifugal in its present form aims at (a) the rapid and efficient isolation of coarser sediments, such as those found in the urine in diagnostic examinations with such powers as two to three hundred diameters. (b) Rapid bulk percentage determinations of chemical deposits, very convenient in uranalysis. (c) Special appliances for bacterial search, whereby enormous centrifugal force may be brought to bear not only upon sputum, but also in concentrating the sediment from such bulky media as the urine, and rendering the manipulation of such minute sediments a matter of extreme simplicity. (d) Including within its range of utility the percentage determination of red and white corpuscles of the blood by means of the ordinary hæmatocrite.

With regard to the use of the hæmatocrite, its description and uses have been so thoroughly gone over by Dr. Daland, of Philadelphia, that it need not be entered into here, nor is anything new alleged for it in connection with the Purdy motor. Its adaptation to this motor is a matter of great simplicity, however, and its addition to this apparatus completes its field of usefulness, which now covers the whole scope of centrifugal work for medical and allied scientific purposes.

**The Twelfth International Medical Congress.**—Dr. Jacobi announces that the congress will be held in Moscow from August 19 to August 26, 1897. The executive committee consists of the following gentlemen: President, Professor I. F. Klein; vice-president, Professor A. J. Kojewnikow; treasurer, Professor N. F. Filatow; secretary-general, Professor W. K. Roth; and secretaries, Professor R. T. Diakonow, Professor W. A. Tikhomirov, and Professor I. I. Neyding. Dr. Claudius H. Mastin, of Mobile, has been appointed to serve as one of the members of the American National Committee. It has been announced that preparations are being made for the reduction of transatlantic steamer and European railroad fares.

\* With all other tubes for sputum and bacterial search the writer has seen, there is no provision whatever for manipulation of the sediment. Ordinary small tubing of uniform size being employed, with no provision for closing either end, the sediment is more often lost in the manipulation than secured. Such tubes are practically valueless for the purposes for which they are designed.

## A CASE OF LAPAROTOMY

WITH THE COMPLICATION OF PREGNANCY FOR DIAGNOSIS.

By M. J. SHIELDS, M. D.

VISITING PHYSICIAN TO THE CARBONDALE, PA., EMERGENCY HOSPITAL.

I SHOULD like to report a rather peculiar case that occurred in my practice, with the hope that some one will make the diagnosis—a case in which all the symptoms pointed toward septic peritonitis complicating pregnancy, in which laparotomy was performed:

On the morning of May 4, 1895, I was called to see Mrs. D., primipara, five months pregnant. She had just had a severe chill that lasted twenty minutes. I found her with a temperature of 104°; pulse 120, weak and small; face a dusky red; features drawn and countenance anxious. She complained of much pain in the left iliac region; abdomen tense and swollen; very tender on pressure, especially so over the left side; tympanitic over the whole of the abdomen. Vaginal examination revealed nothing special except that the whole pelvic contents seemed to be crowded down, as it were. Urine was of high color; specific gravity, 1.025; no trace of either albumin or pus. I saw her again in the evening; temperature normal, fever having passed off with a profuse sweat. She felt better in every respect; her bowels had moved copiously. She complained of pain on urination. Urine scanty.

*May 5th.*—Temperature normal; passed a fairly good night; abdomen still tympanitic and tender; taking some nourishment. I saw her again in the evening. She had another chill at 5 p. m., which lasted longer than the preceding one; temperature, 104.5°; pulse, 128. She complained of great pain in the left side, over the region of the left ovary. I could make out no tumor; the abdomen was more tense and swollen; she had headache and nausea. I examined the urine again, but found nothing to account for the severe symptoms.

*6th.*—Dr. Wheeler and Dr. Gilles, of Carbondale, Pennsylvania, saw the patient with me, but as her temperature was normal and symptoms better nothing definite was decided.

*7th.*—Another severe chill, followed by high temperature and rapid pulse; abdomen very much swollen and tympanitic; the patient slightly delirious. In the afternoon she had a profuse sweat; temperature below normal.

*8th.*—Very severe chill in the afternoon, with the same symptoms. Had another consultation with the above-named gentlemen, Dr. R. Burns, of Honesdale, Pennsylvania, being present. We decided that it was a case of septic peritonitis, after having gone over the case very carefully, and it was decided to open the abdomen, which was done on the morning of the 9th, the patient having a very severe chill while the preparations for the operation were being made. The temperature at the time of the operation was 103.5°, pulse, 130. Dr. Burns performed the operation in the presence of Dr. Wheeler, Dr. Gilles, of Carbondale, Dr. Graves, of Jermy, Pennsylvania, and myself, and found absolutely nothing abnormal. The uterus and appendages, appendix, and kidneys were perfectly healthy. The intestines were slightly congested, but that was all. The wound was closed, and the patient rallied well from the operation, the temperature coming down to 98.5° in three hours after.

10th.—Labor pains came on and she miscarried, having a sharp hemorrhage after the birth of the fetus, which lived a short time. She made an uninterrupted recovery. The abdominal wound was perfectly healed in ten days. In July, 1896, I was called again to see her, and found that she was again pregnant, about five months. She had irregular chills, fever, and sweats for three days, accompanied by the same abdominal symptoms, and on the morning of the third day she had a miscarriage, and made a rapid recovery as before. I examined the urine and found nothing, as before. Now, what was the cause of this train of desperate symptoms which so simulated the absorption of pus? The patient is enjoying good health at the present writing.

JERMYN, PA., October 26, 1896.

#### SUPPLEMENTARY NOTE ON A CASE OF MARTIN'S BRIDGE FOR DEPRESSED NOSE.

By CHARLES H. KNIGHT, M. D.

SINCE the publication of my paper on the Sequelæ of Nasal Syphilis in the *New York Medical Journal* for September 19, 1896, the patient whose case was therein described has returned to my clinic with an unhappy story. Everything went smoothly with him until well on in the summer, when nasal breathing began to be impeded by cicatricial contraction of the anterior nares. His condition became so uncomfortable that it was necessary, during my absence, to cut away some of the cicatricial tissue and insert a vulcanite tube. In his eagerness to keep the nostrils open the patient was in the habit of removing, cleansing, and replacing the tube several times a day, sometimes using a good deal of force. Only a few weeks of this daily disturbance of the bridge, by violent reinsertion of the tube, were needed to accomplish erosion of the skin over the dorsum of the nose. When he reappeared at my clinic the upper end of the artificial bridge could be plainly seen through a perforation in the skin. It now remains to remove the bridge altogether and be content with keeping the nostrils open, or to try to retain the bridge, and cover the skin lesion by some sort of plastic operation. In the former case the original deformity, or worse, will be established. In the latter case it may be advisable to sacrifice the patency of the nostrils, for a time at least, rather than take the risk of disarranging the bridge by putting in a nasal tube. In spite of its failure in this case, and at the risk of seeming to champion a lost cause, I still maintain my confidence in the artificial bridge in suitable cases, and would merely reiterate the conclusions of my paper, especially emphasizing the importance of removing all possibility of tension and friction at the upper end of the bridge by molding it closely to the nasal bones and by making a free dissection of the soft parts. The unusual tendency to cicatricial formations in the foregoing case may be attributed to the repeated cuttings to which the patient was subjected, combined with a persistence of the syphilitic dyscrasia, and

enforces the necessity of postponing surgical interference in specific cases as long as possible, or until the disease may have been thoroughly eliminated by treatment.

147 WEST FIFTY-SEVENTH STREET, November 9, 1896.

#### NOTES ON

#### THE TREATMENT OF DIPHTHERIA.\*

By S. HARTWELL CHAPMAN, A. M., M. D.,

NEW HAVEN, CONN.

THE question of the value of the antitoxine treatment is still undecided. While statistics seem to show that as a remedial agent it is worthy of further trial, yet the number of cases of death from its use as a prophylactic agent would cause us to withhold complete confidence.

It possibly may be therefore of interest to the members of the society present to listen for a few minutes to the report of another and older method of treatment which has seemed to be serviceable in my hands, and of which the statistics show almost if not quite as favorably as those of the more modern treatment.

My note-books give me the histories of thirty-three cases during the past twelve years—a small proportion of cases in comparison with those in the practice of many of the members of the Laryngological Society, but sufficient to enable us to formulate a fair statistical record. The cases are divided as follows: Postnasal, 2; tonsillar, 9; tonsillar-pharyngeal, 11; tonsillar-pharyngeal laryngeal, 6; laryngeal, 5. Seven cases terminated fatally—namely, 2 postnasal, 1 tonsillar, 1 tonsillar-laryngeal, 3 laryngeal.

Of the laryngeal cases, one death was due to the accident of the premature withdrawal of the entire tracheotomy tube by my assistant.

The tube needed cleaning, and while extracting the inner tube the assistant slipped the external out, and before it could be replaced death occurred by asphyxia. Six deaths then in thirty-three cases, or a little more than eighteen per cent. Of these six cases, five were seen in consultation at a stage when the disease had already become general.

In four of the eleven laryngeal cases tracheotomy was performed, with three deaths from general infection. In all of the cases seen and treated during the early stage of the disease, with the exception of one tonsillar, the patients recovered.

The method of treatment adopted was the following, the remedy used being the protiodide of mercury.

The theory of treatment by this drug was supported by experiments upon the behavior of the diphtheritic germ in the presence of numerous antiseptics, made in my own laboratory in the years 1873 and 1874.

\* Read before the American Laryngological Association at its eighteenth annual congress.

The devitalizing power of forms of mercury was found to be the greatest; and of all forms of mercury the protiodide was the most efficient. A solution of one grain to six ounces of sterilized water was the preparation used in these cases, applied in three different ways—first, by hypodermic injection into the submucous tissues surrounding the exudation; second, by deep injection into the tonsillar tissue; and third, by spray upon the pharynx and larynx.

The spray and injections were used simultaneously, a drachm of the fluid being injected two and sometimes three times a day, and the spray used in the intervals between the injections.

Not to take too much of your time, let me, in closing, give the history of three cases in the same family:

In February, 1884, Mrs. W., New Haven, aged forty-three years; well-developed membrane on both tonsils.

Son, aged fourteen years; membrane extending over the left tonsil and one quarter of the left half of the pharynx.

Son, aged six years; no development of membrane for three days; then uniform membrane showing over the entire pharynx and arch, at first appearing like a thin film of milk, but growing in twenty-four hours to a well-formed distinct membrane.

No treatment was given this latter case until the membrane became well defined—simply for the purpose of observation and experiment.

These cases were treated in the manner described, with the result that, first, no spreading of the membrane took place; second, that in twenty-four hours the membrane began to shrivel and dry, and by the end of the third day had in each case been exfoliated and expelled.

As a prophylactic, the mercury seems of some use.

I am not in the habit of isolating cases of diphtheria, but of causing other members of the family to use the spray freely during the continuance of the disease.

This is a case in point:

Child, Clara J., aged five years, March, 1886, New Haven; membrane of the pharynx and brim of the larynx.

The mother begged to be allowed to care for the invalid, although at the time she was nursing a child eight months old. This I allowed, taking the precaution to use the mercury as spray in both cases.

There was no spread of the disease.

In conclusion, let me say that I still use the remedy as described—having gained confidence in it for all cases where constitutional infection has not yet taken place.

**Bellevue Hospital Medical College.**—On Tuesday, December 15th, Dr. T. M. Rotch of Boston, lectured before the students, by invitation, on the subject of the diagnosis of the eruptive diseases of children, with special reference to scarlet fever and its complications. The lecture was illustrated with colored lantern slides.

**Changes of Address.**—Dr. John J. Quigley, to No. 255 West One-hundred-and-thirty-eighth Street, New York; Dr. William Shannon, to No. 117 West Eighty-first Street, New York.

## THE ULTIMATE PHYSIOLOGICAL UNITS OF THE ORGANISM.\*

By M. P. OVERHOLSER, M. D.,  
HARRISONVILLE, MO.

IN the study of the life activities of the body we are confronted with difficulties, for we have to deal with an organism that is complex in its structure and complicated in its functions—an organism that is composed of many different kinds of tissue with manifold physiological activities.

To study the gross anatomy and functions of the different organs of the body will not give us a knowledge of the true physiological and pathological activities of living structure, for the physiological activities manifested by the complex whole are simply the sum, or rather the resultant, of the separate and independent activities resident in each of the ultimate constituents of which it is composed.

To be thoroughly familiar with the workings of any complicated structure necessitates a knowledge of the structure and functions of its ultimate parts.

Notwithstanding the complexity of the tissues and organs of the body they can all be resolved into ultimate anatomical and physiological units. Each organ or tissue is simply an aggregation of morphological elements. These primary tissue elements are alike in similar structures, but differ from each other in unlike structures. A muscle cell is not like a nerve cell, nor a connective-tissue cell like an epithelial cell, yet each cell is a unit of the organism and has a separate and independent function to perform. The complete function of any organ of the body is simply the resultant labor of the independent physiological activities of the cellular units of which it is constructed.

To thus resolve the whole of the human body into its ultimate anatomical and physiological units, and then study the structure and action of each set of primary elements of the different tissues, noting their origin and development from the primitive cells to specialized tissue, would seem to be a rational method of arriving at a solution of the physiological action of the ultimate constituents of the human organism.

But such a comprehensive consideration of our subject in a limited paper like this would not only be impracticable but impossible, for it would lead us beyond the present limits of our science and open to us for investigation many of the unexplained mysterious molecular activities of the protoplasmic cellular structures.

But as the recent progress of medical science by a more careful investigation of the fundamental principles governing the life activities of the cell has led to a new departure in therapeutics and already contributed valuable physiological products for the control of certain diseases, it behooves us to inquire into, and investi-

\* Read before the Hodgen Medical Association at Rich Hill, Missouri, October 1, 1896.

gate as best we can, the normal and abnormal action of these ultimate vitalized constituents of our being.

It is true that many of the hidden mysteries of the organism have not yet been revealed, but be it said to the credit of some of our greatest medical scientists of the day that we believe the dawn of an age of more rational and scientific medication is now approaching, and the faint illumination already observable in the eastern horizon will continue to grow brighter until the day breaks forth in the full brightness and splendor of true physiological therapy.

In the early times of the history of our science the comparison of gross structures of the body gave us important results and taught us much, but these teachings have long since, to a great extent, been exhausted, and the most valuable contributions to our science of to-day are arrived at by an investigation of the histological structure and physiological action of its ultimate constituents.

The human body is simply an aggregation of minute organic units—a mass of cellular elements—many of which have become so widely differentiated from the primary parent cell from which they came that they seem to have lost almost all trace of their primitive protoplasmic existence. These primary, definite physiological and anatomical entities exhibit all the phenomena of life. They are minute individual organisms themselves which form the basis of construction of all living matter, and from which the higher structures of all living things are derived. They are little masses of living protoplasm, or else a modified or specialized form of protoplasmic matter of a higher type of development, with definite form and function. They are not simply a conception of invisible molecular structures of atomic constitution for convenience of description and theoretical teaching, but a microscopical optical analysis of living tissue.

Not only are these primary fundamental forms of life the seat of the normal chemical or chemico-physical activities of vitalized matter, but they also play the part as chief actors in the various pathological dramas of our organism.

To lead up to the prime thought in our paper without leaving you at sea on our subject, and confusing your mind with unexplained assertions and disconnected statements of physiological facts, we will commence our study with the simplest forms of life, and gradually ascend the scale from the simple unicellular organism, with no marked obvious distinction of parts, to the complicated multicellular structure of the human body with widely differentiated structures for its various functions.

Protozoa is the name applied to the lowest grade of the animal kingdom. They are those animals which are structurally single cells, single corpuscles of protoplasm. There are two great grades of this division of the animal world—the corticate and the non-corticate.

In the corticate protozoa we have the primitive step of differentiation of structure. It is here shown by simply a peripheral modification of the protoplasm of the single cell by which it is developed into a cortical layer of denser protoplasm which is distinct from the deeper medullary protoplasm.

In the non-corticate protozoa the cell protoplasm is entirely or partially exposed to the surrounding medium as a naked, undifferentiated, viscous fluid. These forms of protozoa can engulf solid particles of food at any point on their surface or at any point of a large exposed area. On the other hand, in the corticate protozoa we find one or more definite apertures in the cortical layer of the protoplasm through which the cell must receive its sustenance. We have no tissue cells in the human body which present any close parallel to the mouth-bearing corticate protozoa. The best example of the non-corticate protozoa is the amoeba. This is a microscopic fragment of protoplasm that inhabits stagnant waters everywhere. It is a unicellular organism of an undifferentiated structure which moves, eats, digests, and reproduces its kind. It is here that we find the prototype of one of the most important histological structures of our body.

As we ascend from the amoeba we find a very simple though higher form of life in the hydra or freshwater polyp. This consists of a large number of units or cells firmly attached to each other, each cell being composed of protoplasm and in its broad features resembling an amoeba. The hydra is thus a crowd of amoebalike cells so associated as to form two layers in apposition—an internal layer called the endoderm and an external layer called the ectoderm. These layers are so arranged as to form a small tubular body, one end of which is attached to a water weed and the other extremity free for the capture of its prey. The internal layer of cells receives the food and transmutes it, preparing it in such a way that it only needs a few final touches to become living material.

There are no organs within this tubular body. Each cell, like the amoeba itself, digests what it has received in the way of food and then passes its elaborated nourishment on to the outer layer of cells, whose function is movement and feeling. Thus we find that in this simple organism its physiological labor is divided between two membranes or tissues. The prime functions of the inner layer of cells are digestion and assimilation; of the outer layer of cells, motion and sensation. These two membranes differ somewhat from each other in structure. That is, there has been a slight differentiation of the protoplasmic cells. The primitive amoebalike bodies have undergone a slight modification of structure by which they were adapted for a special function. As we ascend the scale of life the most peculiar potency which the amoebalike bodies exhibit, and which is at the bottom of all morphological results, is this force of differentiation. This power is one of the

most mysterious acts of Nature, for we find these protoplasmic cells gradually diverging from their primitive state, passing through a series of stages of gradually increasing divergence, until they reach that condition in which they present the characteristic features of the elements of a special tissue.

In the higher animals the modifications which the primitive cells undergo are so extensive that we lose sight of the primordial cellular elements from which they were developed.

This deviation of structure from the primitive protoplasmic cells in the higher animal life is in consequence of division of physiological labor. In the simple amoeba, digestion, respiration, reproduction, etc., are physiological acts all performed in one cell. In the higher animal life this labor is divided between different organs, each organ requiring a form and structure specially adapted for its work. This gradual modification then of the primitive protoplasmic cells, by which the various parts of an organism are step by step converted into special sets of morphological elements and physiological units which form organs for special function, is called differentiation. The lower the forms of animal life the less the differentiation of structure. An organ of the body is something like a machine for a mechanical or chemico-physical purpose. The work of an organ is its function. Its function is the total work of its units, and its units are simply modified protoplasmic cells—primitive forms of life that have become highly specialized structure for a special purpose.

The physiology of the higher animals is thus merely a development of the simpler physiology of the hydra, which has been rendered more complex by a greater division of physiological labor which necessitates a greater differentiation of structure. By this we do not mean to say that all living beings have come into existence by the gradual modification, through a long series of generations, of a primordial living matter, but that all animal life, whether simple or complex, is developed from a single cell, which in higher life becomes differentiated into two or more parts or germ layers from which all the special organs of that body are derived. We can thus analyze the various tissues of our organism and trace their origin through these steps of divergence from primitive to specialized tissue, and find that from the epiblast are derived the epidermal structures, hair, nails, sebaceous and sudorific glands, central nervous system, optic and olfactory organs, etc.; from the hypoblast, the epithelium of the digestive tract, trachea, lungs, oesophagus, stomach, liver, pancreas, intestines, etc.; and from the mesoblast, connective tissue, lymph glands, spleen, blood-vessels, leucocytes, peritonæum, pleura, kidney, testes, ovary, uterus, and other structures.

Thus we have in the human body many different kinds of specialized structures with as many different kinds of special functions. In short, the body is like a

great machine, with a framework of bones to give it support, with muscles to give it movement, with a force pump to drive the life blood through its channels, with numerous telegraph lines to send dispatches to and from any part of the system, with depurating structures that clear its channels of waste products, and others that receive, prepare, and pour into its canals elaborated material for its use, each part performing its special work, and the sum of the work of its special parts giving us a complete living mechanism, elaborate, intricate, yet so exact in its movements that we wonder at its construction.

In thus viewing our organism we must not become confused or misled in the study of its various physiological acts by its complexity. Nor must we seek to find in these highly specialized structures the true secret of life, for the origin of vital force or the real physiological power of an organism is not in the elements of its highly specialized structures. The office of many of the specialized tissues of the body is largely mechanical, and while they form an indispensable part of the organism in the maintenance of life, yet they concern it only in so far as a failure of their functions interferes with or retards the real life activities of the system.

These differentiated structures of high type of development—the upshot of primitive life—such as muscle cells, nerve cells, liver cells, kidney cells, etc., are subordinate organic elements with no vitalizing power within themselves, except as imparted to them by other living agents, for, “in the physiological division of labor, specialization of function is produced at the expense of the general function, and these cells in performing their special function have special adjustment to the organism, but have lost their equilibrium to the external forces,” and have become subservient dependent cells and can not, like the amoeba, maintain their own existence, complete their cycle of life, reproduce their kind, and then die.

Thus the cells of differentiated structure are not the life-giving units of the organism, but its spendthrifts, for their physiological action is but the expenditure of a vital energy which must be continually supplied them from some other source for the maintenance of their integrity and activity.

In the low forms of life the amoebalike cells take up their nourishment from the surrounding media, and by some mysterious molecular action within themselves the inert lifeless food is transformed into vitalized matter.

These primitive amoebalike bodies are thus found to be the true life-giving units of the organism from which all higher structures of that organism must derive their vital force. This vital energy can not be furnished to any organism except by these amoeboid elements, and if they are pathologically bereft of it there is no possibility ever to supply it by means of their own upshot of

differentiation of structure. The same law of life pervades the whole animal world: "For the laws of life are universal. There is no break in their continuity. They vary in degree, but not in quality. There are degrees of simplicity and complexity, according to the level upon which the particular organism rests with reference to its evolutionary ascent. From the primordial, non-differentiated, homogeneous protoplasm of the protozoon, and from the protozoon to man, vital laws present an unbroken continuity. They do not exist in the cell and cease in the individual. They do not exist in the individual and cease in humanity." (Dr. A. M. Holmes.)

So it follows that if the low forms of life are dependent upon the non-differentiated protoplasmic structures for their vitality, the higher forms of life, being under the same law, are equally dependent upon the same primary unmodified units for their life activities.

Therefore, no matter how widely these specialized structures become differentiated from the primordial forms of life, they always remain subsidiary, dependent units, and must receive their life energy for physiological action from these primitive amoeboid vitalizing agents. This opens to us a great field for investigation, for we find in the human body the analogue of these fundamental forms of life to be the white blood-corpuscle or leucocyte, which resembles the amoeba in many respects, being a microscopic mass of naked protoplasm, many of which, like the amoeba, can engulf solid particles of food at any point on their surface. It presents a central modification of its protoplasmic matter, giving it a nucleus or nuclei and nucleolus. These are the cells of our body which have departed least from the type of undifferentiated protoplasm of the lower animal life and, like the unicellular organisms, they maintain a measurably independent existence. This morphological element is now being considered the real physiological unit of the organism, and is already being acknowledged as the primary seat of all vital action and the agent through which all nutrition is accomplished.

To the action of this little individual structure, in health and disease, the leading investigators in the field of medicine are to-day turning their attention, and the enthusiastic therapist has already declared that he has here discovered the most wonderful agent of therapeutic power yet known to scientific medicine. Be that as it may, it nevertheless behooves us to keep in touch with the latest investigations and teachings along the line of therapeutic medicine, and as physiological therapy—a therapy in accordance with Nature's own methods of cure—is to-day acknowledged as the only rational, effective, and scientific means of combating disease, we should seek to understand the measures she institutes for the cure of her ailments.

In the study of the physiological activities of the body we have to deal with the forces of Nature, and, though our body be composed of a mass of organized units, it is also a continuous, ever-changing mass of

material forces. Life is not an entity, but only the name for the strife or reaction between the internal and external forces of the material world.

By various molecular changes in the organized units of the body these physical forces are displayed as life energies. The normal life forces or life energies of an organism are thus dependent upon certain molecular activities of its units. These molecular activities or reactions proceed in a definite manner, according to fixed laws which govern the interchange of molecules of different substances under certain conditions in a certain media.

Thus, in the study of the life activities of the body, we have to deal with the complicated forces of matter of which our organism is composed. This necessitates a knowledge of the construction and composition of its primary unmodified units. These first and fundamental units of life, as exhibited to us in our organism in the shape of the white corpuscles of the blood, owe their activity to a proteid substance called nuclein. This is the most important constituent of the protoplasmic bodies and the chemical basis of its nuclei. By virtue of this element the cells grow, develop, and reproduce themselves. Its function is to utilize the proteid pabulum gathered up from the blood current by the layer of protoplasm surrounding it. "Until lately we were taught that all nutritious material which had been operated upon by the digestive agents passed directly into the general current of the circulation, floating freely in the plasma of the blood till it reached the capillaries, where it was taken up by the individual cells; but recent investigations prove that these proteid substances of the blood must all report to the leucocytes and be stamped with their nuclear influence before delivery to the tissues." (Dr. Thomas O. Summers.)

"Thus, as soon as these proteids get within the walls of the blood-vessels from the organs of digestion, they are immediately attacked by the leucocytes and taken into the cell walls," where they are acted upon by the nuclein of the white corpuscles, which by a few touches soon transforms the lifeless material into a vitalized pabulum. The leucocytes then scatter throughout all parts of the circulation this "cellulized pabulum," which is taken up by the hungry cells of the several tissues to be utilized in the performance of their work. Thus the white corpuscle becomes the chief agent of nutrition and the primary source of true physiological power. It is the agent which brings about certain molecular changes or motions in lifeless material by which it is transformed into what we call living matter.

Animal life depends, in a large measure, upon the activity of its protoplasm. The more active the protoplasmic matter of its primitive units—these amoeboid elements—the more vital force and vital resistance in the organism.

The nuclear molecule of the white corpuscle is said

to be the most active molecular structure of the body and is wonderfully retentive of life, "possessing marked powers of recuperation after being partly decomposed, as shown by the fact that, after being partly decomposed by salt solution, if this solution be diluted by the addition of large quantities of water the nuclein is restored to its original form." While the function of the white corpuscle as a nutritive vitalizing agent is an all-important one, which could be dwelt upon at much greater length, yet the part it plays in the human economy as a defensive and protective agent is equally as important and essential to life.

Here is a field for investigation that grows broader and broader the more we inquire into the steps taken by these minute physiological units in the preservation of the organism—a field wherein lie many of the unsolved physiological therapeutic powers of our bodies which, when properly revealed, we believe will bring about a greater revolution in the practice of medicine than all the medical teachings of the past. Let us watch these little bodies—for instance, when an irritant seeks to gain an entrance to the blood current: "How they rush by the thousands to the breach and repel their invaders, which are clamoring to get in through a wound, by throwing up their breastworks within the gap, and how fearless and earnest is the struggle, as shown by the dead and dying of the warriors in the shape of pus corpuscles!" We call it inflammation, but it is simply an encounter between the leucocytes on the one side and the micro-organisms on the other. It is a warfare between the invaders from without and the defenders from within—a battle of the cells against the foes which threaten our physical prosperity. Metchnikoff calls it a phagocytic reaction on the part of the organism against the bacterial irritants. The *débris*, in the shape of pus and pus corpuscles, are the dead bodies of these corpuscles of protoplasm which have perished in the struggle.

Thus, as these wandering cells float through the blood-vessels, to and fro along their numerous roads and lines, in close communication with all parts of our body, "they play the part of an active sanitary department, with numerous corps of police stationed in all parts of our system, charged with the function of guarding their possessor against the inroads and attacks of enemies from without which constantly threaten us with disease and death. Thus, inflammation is not to be looked upon as an unnatural and diseased process, but as one which has a true physiological significance in that it is an effort on the part of the leucocytes to save us from the consequences of infection." (Dr. Wilson.)

If the leucocytes do not succeed in repelling the invaders which by some means gain an entrance to the circulation, they attack them with a bold front by rushing upon them and entangling them in the meshes of their protoplasm, where they are digested and assimilated as food by the corpuscles. Thus they act like the

ameba in a liquid containing numerous diatoms and bacteria. If these amœbæ are watched under such conditions they will be found to approach one of these vegetable cells, even though at a distance, and the cell will apprehend and surround it, then take it up into its protoplasm, where it is digested and appropriated to its use. "The amœba has no eyes, no nose, no volition, yet it will approach the particles fitted for its use and swallow them." This swallowing or incorporating of living bacteria by the body cells is called phagocytosis. The force that guides the amœba in its movements is exactly the same as that which governs the movements of the phagocytic cells of the human body. McFarland says that "at the edge of an erysipelas patch a most active warfare is waged between the streptococci and the leucocytes. Near the centre of the patch there are many free streptococci and few cells. At the margin there are free streptococci and a great many streptococci inclosed in leucocytes, which are, for the most part, dead. In the newly invaded tissue we find hosts of active living corpuscles engaged in eating up the enemies as fast as they can." He tells us also that in the centre of such a patch the bacteria are fortified and actively growing. In the next zone, the leucocytes which have feasted upon the bacteria are poisoned by them. Outside, the cells which are more powerful, and which are constantly being re-enforced, are waging successful warfare against the streptococci. In this manner the battle continues—the cells in the centre being obliged to yield to the bacteria and the patch spreading, while the cells subsequently re-enforce and destroy the bacteria, so that the disease comes to a termination. To Metchnikoff, who had studied the process of phagocytosis throughout the animal kingdom, we owe most of our knowledge of the subject. Metchnikoff observed a small unicellular micro-organism, the *microsphæra*, which, however, instead of being digested, multiplied within the amœba and ultimately destroyed it.

Such a struggle between the invading microbes and the protoplasmic cells of the body occurred, according to Metchnikoff, in every case of infection, ending in recovery or death as the cells or microbes were victorious. It is the principle of self-preservation, which is the law throughout the animal kingdom, for when one organism lives in or upon another and feeds at that other's expense, as an unbidden guest, without benefiting its host, there will sooner or later be a contest for supremacy which ends in the survival of the fittest.

Thus we may consider these phagocytic units of our organism as a great army of warriors whose duty it is to meet face to face these living microscopic bacterial enemies that gain entrance to our tissues and eradicate them from our system by consuming them or dragging them off to the lymphatic glands—the dumping grounds of the phagocytes—where they are arrested until they can be disposed of finally.

The more active the protoplasm of these bodies, and

the greater their number, the more likely is success in their efforts to be achieved. The most active white corpuscle of the blood is the multinuclear leucocyte. It possesses the greatest amoeboid movement and is the most active physiological unit of the body. In these various struggles of the organism against the agents that threaten it with disease and death, the multinuclear corpuscle is the chief actor on the field of battle.

These corpuscles are found to increase very rapidly in most all diseased conditions of the system. The increase in the number of these cellular units is called leucocytosis. The first physiological step Nature takes in defense of the body against pathogenic organisms and their toxins is leucocytosis. From nine thousand to ten thousand white corpuscles to the cubic millimetre is considered normal. Bouchut was the first to note an increase in the leucocytes in the blood in diphtheria, in 1868. Since then Pee, Rieder, Limbeck, and many others have found leucocytosis present in the disease. Felsenthal reported the results of the examination of the blood in eight cases of diphtheria. He found leucocytosis in all cases, reaching, in one instance, the enormous sum of 148,229 to the cubic millimetre. In pneumonia, scarlet fever, septicaemia, and in other infectious diseases where the organism has time and vitality sufficient to react against the bacteria and their toxins, we find an increase in the number of the white corpuscles.

We are told there is a relation between the number of leucocytes and the intensity of the diseased process which causes the increase. In pneumonia, it is said, a high temperature in a vigorous subject carries with it a large number of leucocytes. Some one has said that, whether we consider the leucocytes as scavengers and assume that they destroy the cocci in pneumonia, which are the source of infection, or whether we assign to the white cells a share in the production of an antitoxine, certain it is that severe cases in which there is a marked leucocytosis do better, as a rule, than similar cases in which the increase of the cells is relatively slight.

When the leucocytosis is slight, it will be generally found that the system is not reacting energetically against the infection, a condition which suggests an unfavorable prognosis. Ewing, in an article in which he gives the count of the white corpuscles in one hundred and one cases of pneumonia, says that an examination of the deaths will show that in severe forms of lobar pneumonia a slight leucocytosis is a very unfavorable sign, not one case recovering in which the disease was even of moderate severity when the number of leucocytes fell below fourteen thousand to the cubic millimetre. In virulent forms of infection, the condition confronting these white bodies seems to paralyze their action, and they become demoralized by the altered environment to which they are suddenly subjected. Then they no longer present a bold front to the enemy. They are not able to cope with their invaders and the germs run riot through the tissues.

"It is now known that without the rapid leucocytosis caused or rather occasioned by lesions and specific septic germs, no reparation can occur. Retrograde metamorphosis must be promptly met by the re-enforcing legions of leucocytes to build up the shattered walls of the citadel of life, and to meet face to face the troops of toxic germs that are ever rushing to the breach." (Dr. T. O. Summers.)

Not only do the leucocytes play an important part among the natural means of protection of the organism, by their virtue as phagocytes, but they are capable of resisting to a marked degree the poisons elaborated by these disease-producing agents. This brings us to the most important and most promising field of work for the therapist.

Pathogenic bacteria produce their effects on the organism not only by a direct engagement with the leucocytes, but by an elaboration of poisons or toxins which are scattered through the fluids of the body. It is these toxins which are often the cause of death of the organism. Some toxins are intensely virulent, others extremely feeble.

The toxins of the pneumococci are much milder than those of tetanus or diphtheria. The bacilli of diphtheria and tetanus multiply around the seat of inoculation, where there is an active warfare between the phagocytes and bacilli, while the toxins of these bacilli are absorbed and diffused throughout the organism. In septic diseases the toxins are feeble, but the bacteria play havoc in the tissues and fluids of the body. Thus we have to consider not only the power of the leucocyte to destroy bacteria or inhibit their growth, but also the power or capacity it possesses of resisting the effects of their toxins. In septic diseases the safety of the organism is dependent largely upon the number and activity of its phagocytic warriors. In toxic diseases recovery is more largely due to an elaboration by these white cells of a substance which neutralizes the poisonous effects of the toxins on the system. This brings us to an exceedingly interesting subject, the antitoxines, a subject which should interest every practitioner of medicine. I can only stop to mention a few points in connection with these new therapeutic agents, as our time is too far spent to elaborate on the recent developments in this field of work. It is truly wonderful how these protoplasmic corpuscles of the blood can adapt themselves to the different conditions of the media in which they operate. The capacity which they possess of reacting upon their various environments and of bringing about an adjustment to their surroundings seems almost unlimited and is truly one of the most wonderful acts performed by living matter. When the poisons engendered by bacterial agents circulate through the blood the media of these white bodies is changed from a normal to an abnormal condition. This change interferes with the normal action of these protoplasmic units and frequently demoralizes them to such an ex-

tent that the organism dies from what we call toxæmia.

It is only by an elaboration of a product or substance that neutralizes or annuls the poisonous effects of the toxins on the system that the integrity of the tissues is preserved. This neutralizing agent is called antitoxine, and is an entirely new substance which does not occur in the blood of normal animals. It is a protective substance that is not a product of bacterial growth, but a direct product of tissue energy—an entirely new material that is elaborated by the ultimate cells of the body. These antitoxic agents antagonize or neutralize the specific poisons of bacterial origin and thus enable the body cells to endure these injurious changes in its circulating fluids which would otherwise interfere with the normal molecular changes of its units to such an extent as to lead to death of the organism.

This new substance is said to be a product that is elaborated by the least differentiated protoplasmic units of the organism, and thus the white corpuscle again receives the credit of being the manufacturer of the various antitoxic agents required to neutralize the specific poisons of bacterial origin of the various infectious diseases. The important constituent of the white corpuscle, as stated before, is nuclein. We are told that some of the nucleins have germicidal properties more powerful than corrosive sublimate, and that the antitoxic and microbicidal properties of the blood are due to this nuclein substance furnished by the polynuclear white blood-corpuscles.

When bacteria or their toxins enter the circulating fluids of our bodies, or, as some one has said, "when the tocsin of disease is sounded through the organism, it is the rushing of the leucocytes that constitutes the first physiological response. They multiply by the thousands in a short space of time and rush to the scene of action heavily charged with these germicidal and antitoxic nucleins, the greatest weapons of defense that ever have been or ever will be wielded in behalf of the organism against the agents that constantly threaten it on all sides with disease and death."

Here lies the secret of what is called *vis medicatrix nature*—Nature's own curative powers—and here the physician must come to learn how Nature cures diseases, before he is able to administer therapeutic agents that will assist her in the work. To understand this vital resistance, its nature, and its scope, and to increase it in medical practice, is to wield a powerful weapon against disease.

Thus we find in the ultimate analysis of the organic structures of our bodies, from the units of the most highly specialized tissues to the units of simple undifferentiated protoplasm, that the most important organic elements of the organism are the unmodified protoplasmic white blood cells. They are the seat of its physiological powers and the most powerful antagonizers of its pathological conditions; the source of all its

nutrition and of all its repair; its agents of supply in times of peace and its brave warriors of defense in times of battle.

To be able to supply these bodies with the proper weapons of defense in their struggles for existence against disease-producing agents will lead to the development of therapeutic possibilities that we believe will be startling in their results and completely revolutionize the practice of medicine of the coming age. We have not the time, neither did we intend to take up the therapeutic effects of nucleins when administered in diseased conditions of the system. We shall feel amply repaid if the thoughts we have presented will be the means of leading us to investigate for ourselves the therapeutic powers of these important remedial agents.

## Therapeutical Notes.

### Wild Thyme in the Treatment of Whooping-cough.—

The *Journal des praticiens* for November 28th gives the following formula:

R Dried thyme..... 5 parts;  
Boiling water..... 12 "

M. Infuse for ten minutes, sweeten to the taste, and give a tablespoonful every hour.

**Hemicranine.**—This mixture, which we take to be intended for the treatment of hemicrania, is said (*Pharmaceutische Zeitschrift für Russland*, 1896, No. 28; *Nouveaux remèdes*, November 24, 1896) to have the following composition:

Phenacetine..... 5 parts;  
Caffeine, { each ..... 1 part.  
Citric acid, }

**The Medicinal Value of *Salvia Officialis*.**—M. Krahn, in a monograph on this subject (noticed in the *Fortschritte der Medicin* for November 15th), gives a *résumé* of the literature, and says that he has used salvia in thirty-eight cases of profuse sweating, mostly in tuberculous persons. He employs a tincture made with one part of the leaves and ten parts of alcohol, and he has convinced himself of its harmlessness by taking as much as forty drops of it twice a day for six weeks. He has generally given his patients twenty drops in the morning and from twenty to forty drops in the evening. For dispensary patients he orders an infusion made with a tablespoonful of the leaves and a pint of water, of which they take a cupful night and morning. In all but two of the thirty-eight cases it acted favorably, but the action was not sustained when it was given for weeks at a time. Fever is not a contraindication, and he has observed no unpleasant effects.

***Sambucus Nigra* as a Diuretic.**—Lemoine (*Bulletin général de thérapeutique*, March, 1896; *Centralblatt für innere Medicin*, November 28, 1896), on the strength of extensive trials on animals and in practice, warmly recommends the use of a strong maceration decoction of the "second" bark of *Sambucus nigra* as a diuretic especially efficient in dropsy when other remedies have failed and when it is desirable to keep up a diuresis that has been induced by digitalis, caffeine, or the like.

THE  
NEW YORK MEDICAL JOURNAL,  
*A Weekly Review of Medicine.*

Published by  
D. APPLETON & CO.

Edited by  
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, DECEMBER 19, 1896.

PATIENTS' SECRETS MUST BE KEPT.

AT a recent meeting of the Medico-psychological Association of Great Britain and Ireland Dr. Mercier read a paper on alleged exceptions to the rule of secrecy. According to an abstract published in the *Lancet* for December 5th, he thought that the question of professional secrecy was most important to alienists, for to no other physicians were important secrets so often confided, but it was a matter of daily and hourly necessity for physicians who dealt with the insane to decide, often, with no time for consideration, as to the justifiability of considering a case an exception to the rule of secrecy, and yet accusations of unduly and unnecessarily revealing the secrets of their patients had never been made against alienists.

The knowledge imparted by a patient to a medical man as to his disease, said Dr. Mercier, was conceded on the implied obligation of secrecy. He impugned the dogma laid down recently that the medical man must be the sole judge of the circumstances under which the secret of the patient might be published, and proceeded to examine the alleged exceptions to the rule of secrecy. As to evidence in a court of law, he held that there were circumstances in which a man was bound to act according to his conscience, even if in doing so he incurred the terrors of the law. As to revealing the fact of a crime having been committed, he did not consider it part of the duty of the medical profession to transform itself into an auxiliary detective force, and he remarked that it was neither usual nor desirable to use against a patient information obtained under the seal of the medical confessional. As to the protection of the medical man's own wife and children, the admission of such an exception he considered would be so one-sided as to vitiate the contract of secrecy altogether, and he thought it had no foundation in principle or practice. In regard to giving information in order to prevent an impending crime, as there was no legal guidance on this question, individual judgment must be relied upon. Practically the instances seemed limited to one particular crime—viz., the procuring of abortion—as in other cases the knowledge was not usually got from the criminal. The difficulty in cases in which the malady in-

volved danger to the community could generally be effectively dealt with in ways which did not involve the divulging of a professional secret.

Dr. Mercier concluded that a medical practitioner was not under any circumstances justified in revealing the confidence of a sane patient without his consent, and with regard to an insane patient, the information obtained from him might be revealed when, and only when, it was expedient for the welfare of the patient or for the public safety. Dr. Mercier's paper was discussed to some extent, and there seems to have been practical unanimity in agreeing to the principles propounded by the author—principles which, it seems to us, can not be denied.

A RARE RISK FROM ANÆSTHETICS.

AT a recent meeting of the Berlin Society of Obstetrics and Gynecology, a report of which appears in the *Centralblatt für Gynäkologie* for December 5th, Dr. Kiefer showed a specimen of perforation of the stomach by an ulcer after anæsthetization. Four weeks after parturition, in Professor Martin's clinic, the patient had been subjected to a secondary suturing operation, presumably on the perinæum. Previous to the anæsthetization she had been in excellent condition, but she vomited immoderately after it. On the following day she was manifestly in a state of collapse, short-breathed, and complaining of a stabbing pain in the right side. The abdomen was tympanitic, but not very tender on pressure. The pulse was about 120, and there was no elevation of the temperature. She died in about thirty-six hours after the operation. In her last hours she had vomiting of bile, and seems to have gone to sleep quietly after that.

As there were no significant abdominal symptoms, embolism suggested itself at first. When the abdomen was opened post mortem the protruding coils of intestine were accompanied by an abundant escape of liquid that was of a cloudy yellow appearance and smelled aromatic and alcoholic. The peritonæum, including the serous coat of the intestine, showed recent hyperæmia, and was partly covered with lymph. There was a decided hour-glass shape to the stomach, owing to firm adhesions of the cicatricially contracted lesser curvature to the left lobe of the liver in consequence of an old ulcer of the stomach. At the pylorus there was a transverse laceration about two thirds of an inch long through which the mucous membrane was prolapsed; the neighboring portion of the organ was infiltrated with bile, and there was a recent ulcer of the pylorus. The perforation had not given rise to hæmorrhage.

The account leaves it to be inferred that the perforation was due directly to the excessive vomiting that followed the anæsthesia. What anæsthetic was used is not stated. We must probably include ulcer of the stomach among the morbid conditions that render the vomiting incidental to general surgical anæsthesia dangerous. In this instance the ulcer does not seem to have been diagnosed.

## MINOR PARAGRAPHS.

### THE PASTEUR MONUMENT.

As our readers are aware, a monument is to be erected in Paris to the memory of the late M. Pasteur, and the cost is to be met by contributions from various countries. A committee has been formed in Washington to obtain contributions in this country. It consists of Dr. D. E. Salmon, of the Bureau of Animal Industry (chairman); Dr. E. A. de Schweinitz, of the Chemical Society of Washington (secretary); Surgeon-General Sternberg, of the army (treasurer); Surgeon-General Tryon, of the navy; Surgeon General Wyman, of the Marine-Hospital Service; Professor S. F. Emmons, of the Geological Society; Professor Lester F. Ward, of the Anthropological Society of Washington; Dr. William B. French, of the Medical Society of the District of Columbia; the Hon. Gardiner G. Hubbard, of the National Geographical Society; Mr. C. L. Marlatt, of the Entomological Society; and Dr. C. Wardell Stiles, of the Biological Society of Washington. Such a committee, representative of many branches of science, will certainly, it is to be assumed, collect within a short time the amount required from the United States for this most commendable undertaking.

### ANOTHER DOCTOR IN GENERAL LITERATURE.

UNDER the title of *Hopkins's Pond and Other Sketches* the Putnams have issued an attractive book, by Dr. Robert T. Morris, consisting of contributions made to periodicals at various times and now for the first time brought together. Most of the prose articles deal with matters more or less closely connected with shooting and fishing. They are very entertaining; so also are the few character sketches in the volume, and in addition the latter show a considerable insight into human nature. The volume closes with a few pieces of versification that express kindly sentiments. We hope that Dr. Morris will work further in general literature, for he undoubtedly has a decided aptitude for description and narration.

### ITEMS.

**The Buffalo Academy of Medicine.**—At the last regular meeting of the Section in Medicine, on Tuesday, the 8th inst., the order for the evening included the following papers: The Care of Delicate Children, by Dr. Ross; The Feeding of Children under Five Years of Age, by Dr. De Lancey Rochester; The Serum Diagnosis of Typhoid Fever, a Report of a Series of Fifty Cases, by Dr. Frank J. Thornbury and Dr. A. H. Appell; A Controversial Report of Widal's Serum Diagnosis of Typhoid, by Dr. Julius Ullman and Dr. Albert E. Woehner; and A Report of an Unusual Clinical Case, by Dr. G. A. Himmelsbach. At the last

regular meeting of the Section in Pathology, on Tuesday evening, the 15th inst., the following papers were to be read: Perforation of the Uterus, by Dr. Sidney Dunham; Perforating Ulcer of the Intestine, by Dr. N. G. Russell; and Comparative Anatomy of the Cæcum—an Appendix Vermiformis in a Dog, by Dr. A. T. Kerr, Jr. Dr. H. E. Hayd exhibited gynaecological specimens.

**Intectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 15, 1896:

DISEASES.	Week ending Dec. 8.		Week ending Dec. 15.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	43	14	23	9
Scarlet fever.....	105	5	145	10
Cerebro-spinal meningitis....	4	3	0	0
Measles.....	116	1	123	6
Diphtheria.....	245	40	295	35
Tuberculosis.....	149	97	89	83

**The Academy of Medicine's Semicentennial.**—The New York Academy of Medicine will celebrate the fiftieth anniversary of its founding on Friday evening, January 29th, in Carnegie Music Hall. There will be addresses by the President of the United States, Dr. A. Jacobi, and others, and subsequently a reception in the Academy's own building.

**Army Intelligence.**—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from December 6 to December 12, 1896:*

KENNEDY, JAMES M., First Lieutenant and Assistant Surgeon, will proceed to Fort Custer, Montana, and report for temporary duty at that post.

SHANNON, WILLIAM C., Major and Surgeon, is granted leave of absence for one month on surgeon's certificate of disability, with permission to leave the Department of Dakota.

STRAUB, PAUL F., First Lieutenant and Assistant Surgeon, is granted leave of absence for one month.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending December 12, 1896:*

BEYER, H. G., Surgeon. Detached from the U. S. Steamer Raleigh and ordered to the U. S. Steamer Newark.

BROWNELL, C. D., Passed Assistant Surgeon. Detached from the Puget Sound Naval Station and ordered to the U. S. Steamer Petrel.

FITTS, H. B., Passed Assistant Surgeon. Detached from the U. S. Steamer Essex, ordered home, and placed on waiting orders.

MARSTELLER, E. H., Surgeon. Ordered to the U. S. Steamer Raleigh.

PARRISH, H. F., Assistant Surgeon. Resignation accepted from January 1, 1897.

### Society Meetings for the Coming Week:

MONDAY, December 21st: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Cleveland Society of the Medical Sciences; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, December 22d: New York Dermatological Society; Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, December 23d: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Medical Society of the County of Albany, N. Y.; Philadelphia County Medical Society.

THURSDAY, December 24th: New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Pathological Society; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.

FRIDAY, December 25th: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society; Cleveland Medical Society; St. Louis Academy of Medical and Surgical Sciences.

SATURDAY, December 26th: New York Medical and Surgical Society (private); St. Louis Medical Society.

## OBITUARY NOTES.

**Dr. Frederick Arnold Manning**, who died on December 3d in Denver, was a physician of exceptional attainments. He was born in Eddyville, Iowa, on May 4, 1839. He was fitted for college at the Polytechnic Institute in Brooklyn, and graduated in the arts at Yale in the class of 1881. Three years later he graduated in medicine at the College of Physicians and Surgeons. He served for eighteen months on the surgical house staff of the New York Hospital. He then entered upon practice in New York, succeeded in establishing an enviable reputation as a physician and surgeon, and was appointed to various hospitals in positions of trust. In the summer of 1894 he was attacked by pulmonary tuberculosis, and in 1895 he went to Colorado in search of health. The form of his disease was, however, active from the start, and the climatic advantages were unable to check its progress. Dr. Manning was a brave, kind-hearted, unselfish man, and will be sincerely mourned by all who knew him. He was a member of the leading medical societies of New York. He leaves a wife and child. He was buried at South Coventry, Connecticut.

## Births, Marriages, and Deaths.

## Married.

**CARSON—VAN EVRA.**—In Fultonville, N. Y., on Wednesday, December 9th, Dr. Robert L. Carson, of Rochester, and Miss Gertha M. Van Evra.

**COBLENTZ—RAMSBURG.**—In Washington, D. C., on Thursday, December 10th, Dr. Horace B. Coblentz and Miss Lillie R. Ramsburg.

**COX—DEAS.**—In Scranton, Mississippi, on Thursday, December 10th, Dr. William A. Cox and Miss May Deas.

**GAMBLE—JENNESS.**—In New York, on Thursday, December 10th, Dr. Carey Breckenridge Gamble, of Baltimore, and Miss Vera Jenness.

**GARY—BARHAM.**—In Norfolk, Virginia, on Wednesday, December 16th, Dr. Benjamin Roscoe Gary and Miss Willie Alberta Barham.

## Died.

**DAVIS.**—In Rochester, on Thursday, December 10th, Dr. E. H. Davis, aged sixty-four years.

**GILBERT.**—In New York, on Wednesday, December 9th, Dr. James B. Gilbert, in the forty-fourth year of his age.

**KIBBE.**—In Abbeville, Louisiana, on Saturday, December 12th, Payne Kibbe, son of Dr. W. G. Kibbe.

**MANNING.**—In Denver, Colorado, on Thursday, December 3d, Dr. Frederick Arnold Manning.

**SANFORD.**—In New Haven, on Saturday, December 12th, Dr. Leonard J. Sanford, in the sixty-fourth year of his age.

**STROUT.**—In Minneapolis, on Friday, November 27th, Mrs. Henrietta Strout, wife of Dr. E. S. Strout.

**TAYLOR.**—In New York, on Wednesday, December 9th, Dr. George H. Taylor, in the seventy-sixth year of his age.

**WOOLLEY.**—In Newburgh, N. Y., on Friday, December 11th, Dr. Charles N. Woolley, aged fifty-eight years.

## Letters to the Editor.

## ANTIPYRINE AND CALOMEL.

OGDEN CITY, UTAH, December 9, 1896.

To the Editor of the New York Medical Journal:

SIR: I have read with interest the discussion between Dr. Rosenau and Dr. Robinson relative to the toxic effects of antipyrine combined with calomel or when combined with nitrous ether. I have been taught by experience to administer the drugs separately. Twice in my practice I have come near losing a little patient by prescribing antipyrine and nitrous ether, though the two were in no wise combined; in fact, two hours elapsed between the administration of the two medicines. The depression was so pronounced that I invited counsel, and together we worked nearly the whole of a night to keep the little sufferer alive, and only strychnine and whisky, hypodermically used, saved the life of one. The other did not fare so badly. Of course, we resorted to many expedients besides the two mentioned.

If, as Dr. Rosenau suggests, the toxic effects are manifested chemically only when the drugs are mixed in the mortar or phial, still it is well to have a care while administering them and let as long a time elapse between the giving of them as possible. If given together, they may combine in spite of the assimilating power of the stomach, owing to some abnormal condition there.

A. S. CONDON, M. D.

## WHAT BECOMES OF LARGE DOSES OF OLIVE OIL.

VICKSBURG, Miss., November 24, 1896.

To the Editor of the New York Medical Journal:

SIR: The ultimate disposal of olive oil when given in the enormous quantities frequently heard of was until recently unknown to me, but is just what consideration of the circumstances would lead one to expect. That the free and available alkalies of the intestines are all seized upon after the fat splitter, steapsin, has separated the esters into their respective radicles is not to be doubted. Such a large amount could hardly be saponified, emulsified, or absorbed, however, excessive amounts of other classes of foods being refused by the economy. That all of it followed the conventional path is not a reasonable proposition, and a recent case enabled me to determine its fate in at least one instance. A *compère* had a case of hepatic colic in a victim of chronic malarial disease, and gave two pints of olive oil. Subsequently his attention was directed to some peculiar masses in the vessel. He brought them to me, and I found them to be of about the size of marbles, irregular shaped, translucent, of the consistence of cheese, and green in color. The history giving me the cue, I found they were glyceryl palmates colored with oxidized bilirubin. I saponified them with boiling sodium hydrate, precipitated one tube with artificially hard water, and salted out another, getting a hard soap. The gallstone was found, and proved to be deposits of cholesterol crystals around an organic nucleus, presumably of mucus or epithelium. The denser palmates were evidently outclassed in the race by the more unstable oleates and came through unchanged. A close analysis of all the faeces on an exclusive fat diet of determined composition would be most interesting.

A. T. MITCHELL, M. D.

## Proceedings of Societies.

### AMERICAN NEUROLOGICAL ASSOCIATION.

*Twenty-second Annual Meeting, held in Philadelphia, on Wednesday, Thursday, and Friday, June 3, 4, and 5, 1896.*

The President, Dr. F. X. DERCUM, of Philadelphia, in the Chair.

(Concluded from page 432.)

**Edema of the Eyelids in Graves's Disease; Thyroidectomy.**—Dr. J. ARTHUR BOOTH, of New York, read a paper on this subject and exhibited the patient who had been operated upon. He drew the following conclusions: 1. Slight degrees of edema situated in the extremities were of common occurrence in Graves's disease, but this symptom limited to the eyelids was very seldom seen. 2. In distinguishing these various forms of swelling it was necessary to be guided by the position and degree. If situated only in the face and upper limbs, or if asymmetrical, it was entirely of nervous origin, and it might be so if it affected the feet, but it was only slight and temporary. 3. These dropsies were evidently of vasomotor origin and were probably due to paralysis of the vasoconstrictor nerves, and were manifestations of peripheral neuritis. 4. Limited to the eyelids, edema might be due to paresis of the orbicularis. If this was true, however, it was strange that it was not met with in other palsies of this muscle. 5. Thyroidectomy, carefully performed and by one cognizant of the occasional complications, was not such a dangerous operation as was generally believed. 6. From operative interference in Graves's disease we might expect improvement in the rapidity of the pulse, cessation of the disturbing attacks of palpitation, and cure of many of the subjective phenomena.

Dr. STARR expressed the opinion that operations in these cases were not always safe, the percentage of death being twelve out of a hundred and eighty-seven cases. Sudden death had occurred soon after the operation. It had not been due to surgical shock, but to the absorption of thyroid juice during the operation, which overwhelmed the system by its toxic properties. The operation of thyroidectomy should not be done indiscriminately.

**The Nature of Neurasthenia and its Relation to Morbid Fears and Imperative Ideas.**—This was the title of a paper read by Dr. PHILIP COOMBS KNAPP, of Boston. This study was based on a hundred cases seen in hospital practice and fifty seen in private practice. The chief symptoms had been nervousness and weakness, the "irritable weakness" which was considered the essential symptom of neurasthenia. Next in frequency had been headache, indigestion, insomnia, and palpitation. Depression, backache, and other symptoms had been much less common. Neurasthenia had been considered to be analogous to chronic fatigue, and to be due primarily to exhaustion of the cells of the brain cortex. Mental depression was not infrequent, but it was usually secondary to the neurasthenic condition or the physiological result of the causes (grief and worry) which had produced the neurasthenia. Among the morbid fears were, first, those pertaining to the physical welfare of the patient, often based on physical symptoms and having a rational basis, although resting upon false premises and the patient being ignorant of the

significance of these symptoms. In other cases the fears were more those of hypochondria, a mental state akin in some degree to paranoia. The second class of morbid fears were the so-called "phobias," agoraphobia and the dread of insects, snakes, high places, etc. These fears, said Dr. Knapp, existed in perfectly healthy people, who, under their influence, might be thrown into considerable anxiety and distress. In other cases the morbid fears were secondary to certain insistent ideas, as in mysophobia, and, in some cases, the fear of people. These were forms of *folie du doute*. In other forms of *folie du doute* there were insistent ideas with marked speculation, introspection, doubt, and metaphysical quibbling, but without morbid fears. These fears and insistent ideas were not uncommon in mild forms in perfectly healthy persons. In the severe forms they existed as independent psychoses—hypochondriases, the phobopsychoses, and the phobic and speculative forms of *folie du doute*. These different psychoses might exist independently without any trace of neurasthenia; they were to be found in only a small percentage of neurasthenic cases, which was greater among private patients. When found in neurasthenia, these fears and insistent ideas were neither causes nor symptoms of neurasthenia, but indicative of the coexistence of another affection.

**A Form of Mental Disease Clinically Resembling Certain Stages of Paretic Dementia.**—Dr. E. C. SPITZKA, of New York, stated that he had found in a long experience sixteen cases of an affection which was most important to distinguish, as the termination was in recovery. So close had been their resemblance *pro tem*, to paretic dementia that in every instance that or the equivocal diagnosis of softening had been made. The writer himself had at first regarded them as appertaining to Voisin's atheromatous insanity or to his own group of primary mental deterioration. The speech disturbance had been peculiar, having been much like that of febrile delirium. By concentrating his attention, says Dr. Spitzka, a patient could correct his errors, and it was the longest words and those of most difficult enunciation which he pronounced as readily as most persons of average health and education. Repeated trials rapidly fatigued him, and, while no real paretic speech could thus be provoked, he was more apt to say "there is rumthing sotten in the den of state-mark" than to quote the passage correctly. When an expression failed him, he displayed considerable skill in circumscribing his meaning by the use of metaphorical or parallel expressions. A similar feature was found in that similar condition, bromism. The earliest case of which he had a record had occurred in October, 1879, and had been recorded by him as one of chronic confusional insanity, with a reservation as to probable atheromatous sequele. The patient had exhibited typical confusional delirium. His age, sixty-four years, the arcus senilis, the tortuous temporal arteries, and the characteristic pulse had been suggestive. He had been promptly committed to an asylum on Dr. Spitzka's advice. In February, 1881, he had recovered, and he had been alive and in good health three years ago. Among the ætiological factors, syphilis and alcohol could be excluded. Grippe, malaria, railway injuries, dysentery, and chronic bronchitis had played a predisposing rôle. Recovery had occurred in from four to fourteen months. The ages of his patients had ranged from forty-eight to seventy-one years. He had found that the last eleven cases recorded among men exclu-

sively, were not quite two per cent. of a group of cases which included five hundred and eighty-five of parietic dements, forty-one of atheromatous mental trouble, and twenty-eight of primary mental deterioration.

**Nerve Disturbance from Indigestion.**—Dr. HENRY S. UPSON, of Cleveland, dealt with the nervous disorders arising from intestinal indigestion, and reported three cases briefly as follows: A young man twenty-four years old had been seen at the end of the first week of typhoid fever. Besides the typical temperature curves, there were enlarged spleen, nosebleed, backache, and other symptoms; he had even been somewhat delirious during the day, and quite sleepless at night. Thymol and hydrochloric acid had failed to relieve him. A sixth of a grain of morphine with twenty grains of Dover's powder had not produced sleep, and within a week there had been coma vigil and subsultus tendinum. The bowels had been very constipated throughout. During the third week of the disease sleep had followed the clearing of the bowels by calomel very promptly; an eighth of a grain had been given every hour during the day and every two hours during the night. The second case had been that of a merchant, sixty years old. He had been seen two weeks after recovery from a severe attack of dysentery. The diarrhoea had been checked by the free use of opium. He had been in a state of what might be termed restless melancholia. He had been very nervous, cried easily, and hardly slept. There had been rumbling and moderate pain in the bowels, with occasional and somewhat offensive movements. The patient had been given strontium salicylate and calomel, and had been restricted to a milk diet. He had begun to sleep fairly well at night, and his extreme pallor and fairly marked anæmia, with his other symptoms, had improved slowly but steadily. The third patient had shown a similar train of symptoms after a mental shock. There had gradually developed a condition of depression, nervous irritability, and sleeplessness after she had heard suddenly that her husband had accidentally shot himself. She had first been seen five months after this event. In addition to the symptoms already mentioned, she had had rumbling and some tenderness of the bowels, but there had been no diarrhoea or marked constipation. Her condition had improved promptly on a milk diet and on the employment of one of the salicylates. Conclusions, said Dr. Upson, were not warranted from so few cases, but he believed from a somewhat extended experience in these cases that the type of nerve disturbance found in typhoid fever, and in connection with and after dysentery and diarrhoea, was found in intestinal indigestion without the intervention of these disorders, and it might easily be confounded with mild melancholia and neurasthenia; it presented many points of similarity to nicotine poisoning, and it must be carefully distinguished from nerve disorders arising by reflex. It was amenable to treatment, which should not consist exclusively in the administration of an antiseptic.

Dr. J. H. LLOYD exhibited a photograph of a patient with paralysis of the right external rectus and diabetes insipidus which had come on abruptly after an apoplectoid attack.

**The After-care of the Insane.**—This was the preliminary report of a committee composed of Dr. H. L. STEEDMAN, of Boston, Dr. F. X. DERCUM, of Philadelphia, and Dr. C. L. DANA, of New York, in which the establishment of convalescent hospitals for the insane was advocated.

**Newspaper Rabies.**—This was the title of a paper by Dr. IRVING C. ROSSE, of Washington, who referred to the frequency with which hydrophobia was mentioned by the public press at this season. Late papers on the subject showed that there was still a chaotic knowledge of this badly elucidated affection, concerning which surgeons and neurologists were by no means agreed. Dr. Rosse stated that when examining a great mass of literature relative to rabies while working on the *Index Catalogue* of the Surgeon-General's Office, he had come across hundreds of references to hydrophobia of a spurious character, and that these references dated from the Homeric era to that of Cælius Aurelianus. He also cited other literature which showed that in bygone times there had been skeptics as to the existence of such a pathological entity as hydrophobia. He had been an extensive traveler in parts of the world where this disease was supposed to occur, and he had never seen a true case. The secretary of the Japanese legation in Washington had stated that he had never known of a case in Japan, and that in Corea, where there were more dogs than in any other country in the world, hydrophobia was unheard of. A few Italian and French physicians, and the newspapers, appeared to be the chief contributors to the subject at the present time. The speaker thought that, in view of the uncertain state of our knowledge of the subject, the newspapers were hardly to be blamed for their reckless accounts of hydrophobia, since they only held the mirror up to Nature, reflected public sentiment, and gave us, so to speak, a radiograph of what was passing in the minds of medical men.

**The Collateral Theory of Epilepsy.**—Dr. F. W. LANGDON, of Cincinnati, in a paper on this subject, presented the following conclusions: 1. Epilepsy, the choreas, and probably most of the convulsive disorders were the dynamical expression of an inhibitory insufficiency, not indications of overproduction of nerve energy or explosions due to a molecular instability *per se*. 2. The cause of this inhibitory insufficiency was to be sought for in the end brushes of the collateral processes of various cortical neurons, the situation varying with the type of the disease, whether sensory, psychic, or motor. 3. The defect consisted most probably in a structural incompleteness (small capacity, defective insulation, imperfect contact) or a numerical deficiency, or both, in the collateral processes of the neurons referred to. 4. Defective collaterals might favor occurrences of convulsions in two ways: By impairing connection with other neurons (inhibitory), storage, etc., and by increased resistance to "overflow currents" causing temporary overcharging of motor axis-cylinders.

This conception of the anatomico-dynamic basis of convulsive phenomena Dr. Langdon called the collateral theory.

On this basis cases of epilepsy were classed under three groups, each of which presented important differences as regarded prognosis and treatment.

The primary, or developmental, type comprised the idiopathic cases in patients under twenty years of age. In these, the younger the subject and the better the heredity and environment, the better the prognosis under intelligent treatment. The ultimate result depended on the possibility of promoting further and equable development of collateral communications with inhibitory mechanisms. The "accidental" forms were due to injury, syphilis, lead, toxines, etc. The prognosis here varied according to the longer or shorter duration and the possibility of removal of the cause; it was al-

ways favorable so long as permanent structural changes in collateral and inhibitory mechanisms had not occurred. The degenerative type included the rare cases in adult life and old age (not accidental). Here palliation only was to be expected, as in degenerative changes elsewhere. In all forms the rational indications for treatment were to lessen the incoming sensory excitation by diet, occupation, and medicines, and so lessen the intensity of motor responses which were not provided with suitable overflow and inhibitory mechanisms.

### Book Notices.

*A Treatise on Surgery.* By American Authors. For Students and Practitioners of Surgery and Medicine. Edited by ROSWELL PARK, A. M., M. D., Professor of the Principles and Practice of Surgery and of Clinical Surgery in the Medical Department of the University of Buffalo, Buffalo, N. Y., etc. Volume I. General Surgery. With 356 Engravings and 21 Full-page Plates in Colors and Monochrome. Philadelphia and New York: Lea Brothers & Co., 1896. Pp. 6 to 799. [Price, \$4.50.]

ALTHOUGH many members of the medical profession might, at first thought, regard the publication of this treatise upon surgery as an unnecessary addition to our surgical literature, which has so recently been enriched by many valuable contributions, the majority of surgeons who will take the trouble to examine it will, in our opinion, welcome it as a worthy addition, not only on account of the fact that it represents to a large extent the views of its gifted editor, but also on account of its intrinsic worth.

Occupying as it does a position midway between the elaborate and exhaustive treatises on the one hand and the surgical handbooks on the other, it will be found by the surgeon to be a most satisfactory book of reference and by the general practitioner and student of medicine a reliable and convenient text-book. In the first nine chapters, devoted to surgical pathology and the acute infectious surgical diseases, Dr. Park has given us almost classical descriptions of these conditions and processes. His views upon these subjects, which represent the most advanced modern thought, are clearly but briefly stated, carefully considered, and logically expounded.

The chapter on the surgical pathology of the blood contains much that is new and which will be found to be of the greatest clinical value. The same may be said in regard to the chapter on cysts and tumors. It is doubtful if any writer on this important subject has been able to condense so much valuable information into so small a space and at the same time present it in so readable a form.

The chapters on syphilis, anæsthesia, fractures, and dislocations are deserving of special mention, not only on account of the able manner in which the subjects are presented, but also on account of their commendable brevity.

It is to be regretted that the chapter on surgical diagnosis was not more carefully written; although it contains many useful suggestions, it is badly arranged, badly expressed, and in several instances far from accurate.

The work is abundantly illustrated with over three hundred engravings, and a number of excellent full-page colored plates.

If in the general presentation of the subjects the same standard is maintained in the second volume, the work will doubtless receive the general indorsement of the profession.

*A System of Gynecology.* By Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M. A., M. D., LL. D., F. R. C. P., F. R. S., F. L. S., F. S. A., Regius Professor of Physic in the University of Cambridge, etc., and W. S. PLAYFAIR, M. D., LL. D., F. R. C. P., Professor of Obstetric Medicine in King's College, etc. New York and London: The Macmillan Company, 1896. Pp. xviii-973. [Price, \$6.]

A WORK on gynecology published at the present time must, to obtain prestige, have certain inherent virtues. It must be recent in its nomenclature and in its pathological and therapeutical statements; it must condemn obsolete measures unsparingly; it must give something new and not be a mere compilation of other text-books. The book under consideration, with very few exceptions, meets these requirements and more. It is a carefully edited, well written, progressive, recent book, and most of its articles bear the stamp of authority. To point out all the excellences and deficiencies of this system of gynecology would demand more space than can be given in the *Journal*. But it will be worth while to consider a few of the articles more particularly.

The history of the development of gynecology is well presented, full credit being given to German, French, and American investigators. It needs but to be mentioned that the section on the anatomy of the female pelvic organs is written by D. Berry Hart to give it a claim to authority. The chapter on the diagnosis of gynecological disease is by Robert Boxall, and, though it is quite full, it can not be compared to Winter's recent book on the subject, which is of about the same compass as this chapter. For instance, not a word is to be found as to the early detection of pregnancy, a condition which the gynecologist sees much more frequently in its first stages than the obstetrician.

Dr. Playfair himself discusses the relation of the nervous system to the ætiology of disease of the female pelvic organs. Though there is nothing strikingly new presented, the eminent author elaborates the subject with his usual clearness and force. His denunciation of the neglect visited upon young girls during their menstrual development and the false modesty which prevents their being made acquainted with the nature of this phenomenon and its significance is timely, even though it is an off-told tale.

Opinions may differ some years to come as to the curative action of the electric current in gynecological diseases. Yet it is something of a surprise to see electricity so dogmatically recommended as a cure for stenosis, endometritis, subinvolution, and fibrous tumors as is done by Robert Milne Murray. Of endometritis he says: "I am convinced that electrical treatment will cure any case curable by curetting" (page 319). This statement will not meet with hearty indorsement in American gynecological circles. That good results may be obtained in some selected cases of stenosis and fibroids is no longer to be doubted, but thorough dilatation with curetting is a more certain

measure in the former ailment, and operative treatment is to be preferred in cases of fibroids that require interference. The other cases, those in which electricity is beneficial, are usually those which present no marked symptoms in the form of pain or hæmorrhage and therefore demand no treatment.

One of the best chapters in the book is that on displacements of the uterus, by Alexander Russell Simpson. It considers all the operative and non-operative methods of treatment, but the author unfortunately does not express his opinion of the value of vaginal fixation in retroflexion, and he does not mention the mode of action of the pessary in such cases.

Herman has written an admirable article on the disorders following childbirth. There is nothing left to be desired in this or in the succeeding chapter, on extra-uterine gestation, by J. Bland Sutton. Need it be added that Sutton recommends immediate abdominal section, and that only, for this condition?

The articles on pelvic inflammation, pelvic hæmatocele, benign and malignant growths of the uterus, the plastic operations, the diseases of the tubes and ovaries, and the technics of ovariectomy and hysterectomy are all up to the standard of the rest of the work. Of course, in the detailed after-treatment of cases procedures vary, and we fail to see the advantage, for instance, of rectal feeding after hysterectomy and removal of the appendages (page 639). But there is no consensus of opinion as to feeding and the movement of the bowels after the major gynecological operations, and each operator achieves results in his own way.

The book concludes with a comprehensive article on the diseases of the bladder and urethra, by Henry Morris. Although he fails to acknowledge the work of Pawlik and Kelly, the subject is treated with evident knowledge and with more than usual clearness.

It is no disparagement to other systems to say that this work is one of the best, if not the best, in the English language. It is a splendid collection of monographs. The book is handsomely printed on good paper and is richly illustrated. Some of the illustrations are not up to the standard of the best, but many of them are new and are well executed.

#### *A Treatise on Obstetrics for Students and Practitioners.*

By EDWARD P. DAVIS, A. M., M. D., Professor of Obstetrics and Diseases of Infancy in the Philadelphia Polyclinic, etc. Illustrated with Two Hundred and Seventeen Engravings and Thirty Plates in Colors and Monochrome. Philadelphia and New York: Lea Brothers & Co., 1896. Pp. xi-17 to 553. [Price, \$5.]

If the author had been content to designate this work a simple treatise it would call forth less criticism, but in the preface he distinctly states that the aim has been "to furnish to the student a text-book and to the practitioner a work of reference in which the art of obstetrics should be fully set forth in accordance with the most modern results of investigation and experience." Coming as it does from the pen of one who is so intimately connected with obstetric teaching, and who has contributed so many worthy articles in the past, we are forced to the conclusion that for some reason this work has been hurried to the printer without revision or careful thought. A very good example of this deficiency is seen on page 199, where the author, in concluding the subject of the treatment of normal

labor, passes over to the subject of surgical shock as follows: "Should surgical shock be present, it must be treated with strychnine a twentieth of a grain hypodermatically." That strychnine may at times be useful in surgical shock is very certain, but that the medical student should be led to suppose that such is all the treatment required seems to be poor teaching. It is true that under the head of hæmorrhage, in the latter part of the book, this subject is more fully gone into, but the fact should be stated. Surely elevation of the foot of the bed in shock due to hæmorrhage is more efficient than the use of any drug.

The illustrations are many of them new and exceedingly good, but they lack uniformity, and must mislead the student. For example, the surgeon during the examination before delivery not only covers the abdominal wall of the patient with a sheet, but is himself clothed in a surgical gown, while the cuts from photographs upon the management of the different stages of labor, and even suture of the perinæum, show the operator with his ordinary coat removed, and not even his shirt sleeves rolled up. No one can know better than the author himself how apt the medical student is to jump at conclusions, and if he sees in his preceptor's textbook photographs which depict a careless costume during an operation, he probably will feel that he is justified in following his example.

To the reader whose knowledge of obstetrics is advanced this work will undoubtedly prove interesting, as one finds many original ideas within its covers. The text is divided into seven sections as follows: 1, Pregnancy and Labor; 2, Pathology of Labor; 3, Obstetrical Operations; 4, Abortion, Extra-uterine Pregnancy, and the Puerperal State; 5, Infancy in Health and Disease; 6, Diseases of Infancy; 7, the Jurisprudence of Obstetrics. The chapters on development are concise and yet sufficiently full to give a clear idea of the subject.

The section on the pathology of pregnancy is a very good outline of the diseases usually met with, but some of the readers of this work will not perhaps agree with the author that "all women with damaged kidneys should not marry."

The subject of toxæmia is worthy of note, as being rarely dealt with in text-books.

Normal and abnormal labor are well described and the matter is thoroughly modern, but in the section on the pathology of labor, eclampsia and septic infection have not received the study that subjects so important demand.

Obstetrical operations are considered in some sixty pages, and the various procedures are described. The detail is poor, however, as, for example, in the description of the sterilization of the forceps.

Thus, while many subjects are well treated of, there is, nevertheless, evidence throughout of a lack of thoroughness and an unevenness of treatment which can be ascribed only to too hurried work on the part of the author.

*Anatomical Atlas of Obstetrical Diagnosis and Treatment.* By OSCAR SCHAEFFER, M. D. With One Hundred and Forty-five Illustrations. New York: William Wood and Company, 1896. Pp. xvi-234.

THIS volume deals with the morphology of the female pelvic organs as the anatomical basis of the physiological and pathological phenomena of pregnancy and labor.

As a very useful and instructive aid to those working

in the field of obstetric training the book will be most acceptable. If any criticism could be suggested, it would be that the illustrations are not all drawn to the same scale. They are, however, well executed and, the coloring being remarkably good, form a collection of pictures which will be welcomed by the obstetrician. The work contains one hundred and forty-five illustrations in all, and these occupy the first fifty-six pages; the remaining one hundred and seventy-eight pages are devoted to the text, which is divided into nine parts, as follows: Part I, The Normal Anatomy of the Sexual Organs during Pregnancy; Part II, Pelvic Deformities and their Influence upon Pregnancy and Labor; Part III, Displacements, Tumors, and Abnormalities of Development of the Sexual Apparatus, and their Influence upon Pregnancy and Labor; Part IV, Rupture of the Uterus and Lacerations of the Cervix; Part V, Abnormal Implantation of the Ovum, Extra-uterine Pregnancy, and Placenta Prævia; Part VI, Anatomy and Ætiology of the Premature Expulsion of the Ovum; Part VII, Abnormal Presentations, Abnormal States of the Funis and Membranes, Premature Detachment of the Normally Implanted Placenta; Part VIII, Disturbances of Labor caused by Abnormal Uterine Contractions and by General Diseases of the Mother; and Part IX, General Observations on Obstetric Therapeutics.

*A Text-book of Materia Medica, Therapeutics, and Pharmacology.* By GEORGE FRANK BUTLER, Ph. G., M. D., Professor of Materia Medica and Clinical Medicine in the College of Physicians and Surgeons, Chicago, etc. Philadelphia: W. B. Saunders, 1896. Pp. 11 to 858. [Price, \$4.]

The classification adopted by the author of this book follows the lines usually laid down in text-books on materia medica. His work begins with a list of the pharmaceutical preparations, and includes many of the formulæ of the *National Formulary*. These are classified according as they are "solutions," "liquid mixtures," "extractive preparations," "solid mixtures for internal use," etc. The precise value of this arrangement is not easy to perceive, unless it is that the student shall be encumbered with a mass of formulæ which he is not otherwise expected to learn. The author groups the remainder of his material into "disease medicines"—which is very bad English and difficult to understand—"antiseptics" and "symptom medicines." The work ends with some good advice as to prescription-writing and with the usual clinical index.

The text is, in the main, good. It does not go far from adopted teachings in the majority of instances. But there are some statements which may rightly be questioned. The author's dictum that ethyl bromide greatly irritates the air-passages (page 407) will not bear very close investigation, and it will not be generally admitted that children may take large doses of conium, belladonna, arsenic, and mercury with impunity (page 32). These are but two examples selected from a work which possesses not infrequent errors and, at times, considerable vagueness of expression. There are a few important omissions and a few unimportant ones. The author should have said something, for instance, of the occasional disagreeable phenomena that are sequels to the subcutaneous use of cocaine. He speaks of "systemic effects" sometimes following the local application of the drug, but he does not tell how to guard against them or what they are. The methods and time

for administering quinine form a legitimate part of a text-book on materia medica, but no mention is made of them here. The effects of heat and cold are not given, and oxygen is nowhere spoken of.

The book has some virtues. There is a full discussion of serum treatment, traced historically, advocating the antitoxine treatment of diphtheria and properly questioning the curative effects of erysipelas toxine in carcinoma. Four pages are given to treatment with animal extracts, but the author contents himself with giving the impressions of many writers without stating his own opinion as to the worth of such measures.

The illustrations had better have been omitted. That of strychnine poisoning, that of gelsemium poisoning are incorrect, and the diagram (page 543) showing how digitalis relieves the symptoms of mitral disease is almost devoid of meaning. The book is very well printed on good paper and is handsomely bound.

*Skiascopy and its Practical Application to the Study of Refraction.* By EDWARD JACKSON, A. M., M. D., Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. Second Edition. With Twenty-seven Illustrations. Philadelphia: The Edwards & Docker Company, 1896. Pp. 7 to 108.

The fact that the first edition of this work has been exhausted within the year is an evidence that working ophthalmologists have shown a decided interest in the subject. Skiascopy should certainly be more generally adopted by the ophthalmologist as an essential aid in the examination for ametropia. Dr. Jackson's aim has been to endeavor to convince the ophthalmic surgeon of the practical value of this test as a means of shortening an examination, and the little book is not only an example of the thorough theoretical treatment of the subject, but also a very practical presentation of the whole method.

The book consists of eight chapters, and one of the most valuable of them is the first, which explains how to study the test. In the second chapter we have a consideration of the general optical principles involved, and in the third chapter there is an intelligible discussion of the conditions of accuracy for the successful employment of the test. Chapters IV and V are devoted to a consideration of the value of the method in determining regular and irregular astigmatism. The author prefers to use the plane mirror in testing, and in this we think that most ophthalmologists will agree with him. But one chapter is devoted to a discussion of the practical application of the method of examination with the concave mirror. The relative advantages of the plane and concave mirrors are fully set forth in the final chapter. The book well deserves its success.

*Alterations of Personality.* By ALFRED BINET, Director of the Laboratory of Physiological Psychology at the Sorbonne (hautes études), Paris. Translated by HELEN GREEN BALDWIN, with Notes and a Preface by J. MARK BALDWIN, Professor in Princeton University. New York: D. Appleton & Co., 1896. Pp. xii-356.

Not only the scientific world but the educated classes among the laity as well are interested in the series of remarkable psychological investigations and results which started in France some fifteen years ago and have become part of the subject of thought of the present day.

Among the prominent investigators of the mysteries of the mind, Alfred Binet has for a long time been conspicuous; in part because of his originality, in part on account of his fairness of judgment and calmness of decision.

The book just translated has been widely known since its publication, five years ago, in the original French. The author's aim is to establish an interpretation of some of the peculiar manifestations of avowedly normal activity by arguing from cases of double personality which rest upon strong evidence for their classification. He next studies some of the phenomena shown by hysterical persons as occupying a middle ground between normal man and those who give evidence of changing personality. While his conclusions will not perhaps be universally accepted, the book is full of interest to every one who occupies himself with the higher thought of the day.

The work of the translator is admirably done, but is slightly embarrassed, perhaps, by the difficulty of translating words for which we have no exact equivalent in English. Professor Baldwin's notes of reference are helpful to the reader. The publishers' work is handsomely done.

*The Medical and Surgical Uses of Electricity.* By A. D. ROCKWELL, A. M., M. D., Fellow of the New York Academy of Medicine, etc. Illustrated with Two Hundred Engravings. New Edition. New York: William Wood & Co., 1896. Pp. xvi-612.

THIS is practically the ninth edition of Beard and Rockwell's treatise on the same subject. The book, as might be expected, is much changed from the earlier editions, being in accord with the advance in our knowledge of the applications of electricity. The chapters on electro-physics are very good, and present the subject in a clear and forcible manner. The explanation of Ohm's law is lucid, and there is no excuse for the reader's not understanding that very simple but now frequently misunderstood axiom which really lies at the root of all electrical knowledge. The forms of batteries more commonly in use are described, and directions given for their care. Very little attention is paid, however, to the alkaline batteries, which from their manifest advantages are best adapted to the physician's office. A very complete description of the various forms of apparatus on the market is given, and their special advantages are emphasized.

The chapters on the general therapeutic and physiological action of electricity have, as the author states, been little changed from those in the earlier editions.

The different currents of electricity and their therapeutic applications are discussed generally, and afterward the diseases amenable to electrical treatment are taken up in order and the methods of treatment detailed.

Only a single chapter is devoted to the static machine, and little mention is made of the induced currents of high frequency obtainable from it.

The chapters on electro-surgery give a lucid explanation of the rules to be observed in electrolysis and in the use of the galvanocautery.

The application of electrolysis, however, in the treatment of malignant growths, instead of the knife, seems not only absurd but wrong. It is practically the caustic treatment without its efficacy. We are glad to see that the electrolysis of urethral strictures is not favorably considered.

Space is given to the description of various diagnostic apparatus, such as the telephonic bullet probe, but none to the electric light in transillumination and in the direct inspection of visceral cavities.

The book ends with a short account of the Röntgen rays, but does not enter into detailed consideration of them.

On the whole, the work is valuable and will seem to clear up many points which may be shadowy in the mind of the general practitioner.

*The Diary of a Resurrectionist.* 1811-1812. To which are added an Account of the Resurrection Men in London and a Short History of the Passing of the Anatomy Act. By JAMES BLAKE BAILEY, B. A., Librarian of the Royal College of Surgeons of England. London: Swan, Sonnenschein, & Co., Lim., 1896. Pp. xii-13 to 184.

WE of the present day may felicitate ourselves upon the ease with which we acquire subjects for dissection and upon the promise of quiet sepulture—if we desire such disposition of our mortal remains when we have completed our cycles of usefulness. The student of the history of the medical profession knows well the troublous times of anatomists during the last century and the first third of the present one. He knows, too, of the horrors of the days of Burke and Hare and of the fear of the inhabitants of Great Britain of speedy disinterment and almost as speedy dissection.

In the present volume Mr. Bailey prints for the first time the diary of one of the resurrectionists, probably Joshua Naples, and precedes the diary proper with a lucid and learned discussion of the laws relating to anatomical material. While he gives many examples of the methods and work of the resurrection men, he traces the evolution of the Warburton act of 1832, which with slight modifications is the dissection law of England now and the basis of most of our laws relating to the subject. Mr. Bailey has evidently studied his material well. He has written a most instructive little book, which is an unquestionable addition to the history of the period. The value of the book is enhanced by an illustration of the dissecting room by Rowlandson, an old print, and by several interesting photographs and drawings. The book is handsomely made.

#### BOOKS, ETC., RECEIVED.

A Text-book of Bacteriology, including the *Ætiology* and Prevention of Infective Diseases, and a Short Account of Yeasts and Molds, Hematozoa, and Psorosperms. By Edgar M. Crookshank, M. B., Professor of Comparative Pathology and Bacteriology, and Fellow of King's College, London. Fourth Edition, reconstructed, revised, and greatly enlarged. London: H. K. Lewis. Philadelphia: W. B. Saunders, 1896. Pp. xxx-715. [Price, \$6.50.]

*Illustrated Skin Diseases.* An Atlas and Text-book, with Special Reference to Modern Diagnosis and the most Approved Methods of Treatment. By William S. Gottheil, M. D., Professor of Skin and Venereal Diseases at the New York School of Clinical Medicine, etc. New York: E. B. Treat, 1896. Pp. 13 to 84. [In three portfolios; price, each, \$1.]

*Medicine and Kindred Arts in the Plays of Shakespeare.* By Dr. John Moyses, Large Fellow of the Faculty of Physicians and Surgeons, Glasgow. Glasgow: James MacLehose & Sons, 1896. Pp. xiv-123.

The Physician's Visiting List for 1897. Philadelphia: P. Blakiston, Son, & Co., 1896.

Hopkins's Pond and other Sketches. By Robert T. Morris. New York: G. P. Putnam's Sons, 1896. Pp. vii-227.

Traité de médecine et de thérapeutique. Publié sous la direction de MM. P. Brouardel, membre de l'Institut, etc.; A. Gilbert, professeur agrégé à la Faculté de médecine de Paris, etc., et J. Girode, médecin des hôpitaux de Paris, etc. Tome premier. Maladies microbiennes. Par MM. Girode, Auché, Surmont, Galliard, R. Wurtz, Grancher, Netter, Thoinot, A. Legroux, Hudelo, Boulloche, F. Vidal, Courmont, L. Landouzy, Gilbert et Brouardel. Paris: J. B. Baillière et Fils, 1896. Pp. vii-818.

The Doctorate Address delivered at the Commencement of the Illinois Medical College. By Seth Scott Bishop, M. D., of Chicago. [Reprinted from the *Journal of the American Medical Association*.]

A Clinical Study of Twenty-one Thousand Cases of Diseases of the Ear, Nose, and Throat. By Seth Scott Bishop, M. D. [Reprinted from the *Journal of the American Medical Association*.]

Adenoid Vegetations in the Vault of the Pharynx. By Seth Scott Bishop, M. D. [Reprinted from the *New Albany Medical Herald*.]

Acute Suppurative Inflammation of the Middle Ear; Acute Suppurative Mastoiditis; Abscess of the Neck; Operation. By Seth Scott Bishop, M. D. [Reprinted from the *Laryngoscope*.]

Three Cases of Plastic Nasal Surgery for Saddle-shaped Nose, removal of the Entire Nose, and Arched Roman Nose. By W. W. Keen, M. D., of Philadelphia. [Reprinted from the *Therapeutic Gazette*.]

A Successful Case of Removal of a Large Brain Tumor from the Left Frontal Region—Opening and Packing of the Lateral Ventricle with Iodoform Gauze. By H. M. Thomas, M. D., of Baltimore, and W. W. Keen, M. D. [Reprinted from the *American Journal of the Medical Sciences*.]

Some of the Effects of Chronic Nasal Obstruction. By Charles N. Cox, M. D., of Brooklyn. [Reprinted from the *Brooklyn Medical Journal*.]

Description of a Few of the Rarer Complications occurring during and following Cataract Extraction. By Charles A. Oliver, M. D. [Reprinted from the *Archives of Ophthalmology*.]

## Miscellany.

**The Disinfecting Action of Sodium Hypochlorite.**—In the *Lancet* for November 28th Dr. E. Klein gives a detailed account of a series of experiments undertaken by him in which sodium hypochlorite in solutions in distilled water—one in ten, one in a hundred, and one in two hundred—was tested on the following microbes: The *Proteus vulgaris*, the *Bacillus coli communis*, the *Bacillus typhosus*, the *Bacillus diphtheriæ*, the bacillus of swine fever, the vibrio of cholera asiatica, the *Staphy-*

*lococcus aureus* of ordinary pus, the spores of *Bacillus anthracis*, and the spores of the anaerobic *Bacillus enteritidis*. The experiments made with these nine species of microbes were as follows:

**Series 1.**—Sodium hypochlorite was used in a solution of one in ten, that is, containing one per cent. of available chlorine. After exposure for twenty minutes the result was that in no subculture was there any growth; the microbes had been devitalized by this solution in twenty minutes. After exposure for ten minutes the result was that there was no growth in the first seven species or in the spores of the anaerobic *Bacillus enteritidis*, but in the spores of the *Bacillus anthracis* there was a limited growth in broth culture, and in agar culture there was a single colony. On subculture this yielded normal growth which produced typical anthrax in a guinea-pig. While the solution one in ten completely devitalized the spores of anthrax in twenty minutes, it did not quite do this with all the spores. The seven microbes referred to were also killed by an exposure for five minutes, no subculture yielding growth. The spores of the *Bacillus anthracis* and of the anaerobic *Bacillus enteritidis* were seemingly unaffected, since copious normal growth was obtained in subculture.

**Series 2.**—Sodium hypochlorite was used as a watery solution, one in a hundred—that is, 0.1 per cent. of available chlorine. The following bacilli were devitalized after exposure for twenty minutes, and there was no growth in the subculture: The proteus, the *Bacillus coli*, the *Bacillus typhosus*, the *Bacillus diphtheriæ*, the bacillus of swine fever, the vibrio of cholera, and the staphylococcus. The spores of anthrax and of enteritis yielded normal and abundant growth. After exposure for ten minutes the same result was obtained as before; after exposure for five minutes the same result was also obtained. It follows, therefore, from this series, that sodium hypochlorite in a solution of one in a hundred disinfects the non-sporing microbes mentioned above in five minutes, but does not do this with the spores of anthrax and those of the *Bacillus enteritidis* in twenty minutes. The time of exposure for the spores of these two microbes was then prolonged to thirty minutes, to an hour, to an hour and a half, and to two hours. The result was that the anthrax spores, which were exposed for thirty minutes to the disinfectant, one in a hundred, yielded in subculture normal and copious growth, both on agar and in broth. The same spores after an hour's exposure yielded no growth in broth and a limited number of colonies on agar. After exposure for an hour and a half and for two hours no growth took place. Spores of the *Bacillus enteritidis* which were exposed for thirty minutes yielded good growth. The same spores after an hour's exposure yielded a very limited number of colonies. After exposure for an hour and a half and for two hours no growth was yielded. From these experiments it follows that the sodium hypochlorite used in solution of one in a hundred had a complete disinfecting power on both anthrax spores and enteritis spores when acting for an hour and a half; its disinfecting power was limited when acting for an hour, but it had no effect in thirty minutes. This result of the solution of one in a hundred on spores of anthrax (complete disinfection in an hour and a half) compares most favorably, says Dr. Klein, with all disinfectants that he is acquainted with exclusive, of course, of mercuric bichloride.

**Series 3.**—Sodium hypochlorite was used as a watery solution, one in two hundred—that is, 0.05 per cent. of

available chlorine. In this series, also, the time of exposure was for twenty minutes, for ten minutes, and for five minutes. The microbes used were: *Proteus vulgaris*, *Bacillus coli*, *Bacillus typhosus*, *Bacillus diphtheriae*, bacillus of swine fever, vibrio of Asiatic cholera, and *Staphylococcus aureus*. All these succumbed to the action of the solution after a five minutes' exposure, so that no subcultures were obtained in any of the culture tubes. Of course, exposure for ten and twenty minutes respectively had a *fortiori* the same result. On the spores of *Bacillus anthracis* and those of *Bacillus enteritidis* this solution had practically no effect, as even after exposure for four hours good and copious subcultures were obtained.

It follows, then, that on non-sporing microbes the solution, one in two hundred, of sodium hypochlorite acts as a disinfectant in five minutes. Weaker solutions—that is, one in three hundred and one in three hundred and fifty—required an exposure so long that for practical purposes it must be considered as not applicable, as the *Bacillus coli*, and particularly the *Staphylococcus aureus*, which were exposed to the solution, one in three hundred, for three hours yielded in subculture good and normal growth. An indication of the positive disinfecting action of the solution of sodium hypochlorite on the microbes in these experiments is noticeable already by simple inspection of the microbic emulsion. It is this: The emulsion becomes changed from the original turbid into a clear solution; this clarifying action is in proportion, in point of time, to the strength of the sodium hypochlorite solution. Using it in the strength of one in ten, its clarifying action is already noticed in from two to three minutes on the emulsion of non-sporing microbes; an emulsion of spores of anthrax is transparent already in ten minutes.

**Series 4.**—In this series sewage as passed out of St. Bartholomew's Hospital was mixed with sodium hypochlorite. A measured quantity of the sewage (ninety-nine cubic centimetres) was put in a glass-stoppered sterile bottle and to it was added a cubic centimetre of the disinfectant. Consequently there was here a solution of sodium hypochlorite of one in a hundred. The untreated sewage was tested for the number of living microbes contained in it, which was found to be a little under three millions to a cubic centimetre. After shaking up the ninety-nine cubic centimetres of sewage with a cubic centimetre of sodium hypochlorite, subcultures with three platinum loops to a tube were made in broth and on agar, and for anaerobes in deep grape-sugar gelatin. The first two were kept at a temperature of 98.3° F. for four days and the sugar gelatin culture at 68.5° for six days. After thirty minutes all the culture tubes remained free of growth. After twenty minutes there was no growth in the aerobic cultures, but there was one colony in the anaerobic culture; this proved to be a colony of *Bacillus butyricus*. After ten minutes there was copious growth on the agar surface, which proved to be a pure culture of the sporing *Bacillus mesentericus*, but no growth in the broth culture. It follows from this that all non-sporing microbes of the sewage were killed in ten minutes by the addition of a cubic centimetre of sodium hypochlorite to ninety-nine cubic centimetres of sewage. Spores, however, both of the aerobic bacteria (*Bacillus mesentericus*) and of the anaerobic (*Bacillus butyricus*) were not disinfected in ten minutes, but appeared to have been destroyed in thirty minutes. This last result does not quite coincide with the results obtained with the spores directly experimented with in

the former series (Series 2), in which the one-in-a-hundred disinfectant did not harm the spores of anthrax and of enteritis. The spores of *Bacillus mesentericus* having a greater resisting power to inimical influences (heat and chemical disinfectants) than those of *Bacillus anthracis*, and the latter withstanding the action of the sodium hypochlorite solution, one in a hundred, for thirty minutes, the result of the apparently successful disinfection of the spores of the *Bacillus mesentericus* in twenty minutes seems at first sight unintelligible. It is, however, explained if we remember that in the experiments with the spores of anthrax (Series 2) three loops of the emulsion would contain an enormous number of spores, while three loops of the sewage may fail to contain a spore of the *Bacillus mesentericus*, this microbe or its spores being far less numerous in the sewage than in the emulsion crowded with the spores of *Bacillus anthracis*.

The addition of one part of sodium hypochlorite to a hundred parts of the fluid is sufficient to devitalize non-sporing microbes in sewage or any similar fluid in ten minutes.

**The Medical Department in Time of War.**—The *Boston Medical and Surgical Journal* for December 10th publishes an address by Dr. Louis A. La Garde, of which the following is the substance: Medical officers, says the author, are assigned by the chief surgeon, under the orders of the general in command, to the various duties involved in the administrative and executive branches of the medical department. The members of the hospital corps are likewise organized into two branches, one for duty in the field hospitals proper as cooks, nurses, clerks, apothecaries, etc., and the other as drivers of ambulances, as porters for collecting and removing the sick and wounded, and for rendering first aid to them.

With regard to the present allowance of sanitary soldiers and medical officers, Dr. La Garde says that the number of medical officers with troops in the field is on an average three to each regiment, although this number is by no means constant, and it is possible at times to get along with much fewer, while certain emergencies are likely to arise when two or three times that number might be required. In addition to this force of the hospital corps and medical officers, the regulations provide for an auxiliary force among the privates of the fighting line. These are known as litter-bearers. Formerly they numbered four to each company, and they were taught the duties of first aid to the injured by the medical officers. Recent orders from the War Department, however, provide that not only four, but all the men of a company, shall be taught the duties of first aid to the injured, so that in time of battle any one of the men may be designated by the commander to remove the wounded or care for them in other ways.

The medical officers are no longer expected to instruct these privates; they are taught the duties of first aid, and are drilled in the handling of the wounded on and off the stretchers, in and out of the ambulances, etc., by the company officers. The ambulances are distributed to the army at the rate of three to each regiment of infantry of five hundred men or more, two to each cavalry regiment, and one to each battery of artillery. Two ambulances are allowed the headquarters of each army corps, and to each train of ambulances belonging to a division two army wagons are allowed. This, says Dr. La Garde, is the method of organiza-

tion of the medical department in the army on a war footing.

Concerning the question of the necessity of an increase in the number of helpers to the wounded, which seems apparent with the use of the new military rifle, with the old arm experience showed that the numbers already mentioned were sufficient to care for the wounded in the vast majority of instances, but now that the large-calibre rifle has been discarded for the weapon of small bore, whose range and penetration exceed anything yet tried in the way of hand weapons, it is maintained by many writers that there will be a larger percentage of wounded, and that the additional work to be thus imposed upon the relief corps will be far beyond the capacity of the present allotment.

It is said, continues the author, that other causes will operate to impose additional work upon the relief corps by which troops are spread over more ground, and the increase in the percentage of wounded, which it is said will come from modern field artillery.

If the casualties of battle are to be greater hereafter, there is no doubt, Dr. La Garde thinks, that the numbers of the relief corps should be increased. There are no means of estimating the deadliness of the new military rifle—this can only be determined by future wars—but some deductions can be drawn from the statistics of the past, by which conclusions of reasonable value may be arrived at.

A study of these statistics gave formerly a pretty accurate idea of the percentage of the wounded which might be expected in a given battle fought with the old arm. In estimating the casualties of battle heretofore, the percentages of wounds from rifles, carbines, and revolvers were especially considered, because they formed the vast majority of all the wounds noted. The wounds from the artillery arm, bayonets, and sabres formed but a fraction of the whole. It is known from past experience, therefore, says Dr. La Garde, that the great majority of the injured noted in hospitals suffered from bullet wounds. The statistics of various wars shows this very prominently. The statistics of the Crimean War give the percentage of the gunshot wounds by rifle bullets as sixty. In the War of the Rebellion the nature of the missiles was ascertained in 141,961 cases, and the surgeon-general's report says 90.1 per cent. were inflicted by rifle bullets. In the Franco-Prussian War Chenu's statistics gave the percentage of those receiving bullet wounds among the French at Gravelotte at 80.19. The same author on the part of the German army for the whole of the war shows that ninety-one per cent. of the wounds were inflicted with rifle bullets. It is thus seen that heretofore the casualties of battle have been especially identified with bullets from hand weapons, and in reckoning upon the casualties and havoc of future wars, Dr. La Garde believes that the majority of the writers have special reference to the perfected military rifle-propelling, steel-armored bullets. Those who argue that the present allotment of two per cent. for a relief corps is not sufficient, cite especially the dangers of the new gun in so far as they lie in greater penetration, greater dangerous space, and the employment of smokeless powders, which gives a clear field.

It may be stated here, says Dr. La Garde, that increased penetration, superior velocity, and extended range have ever been the aim of the ballisticians, and that the perfected military rifle of to-day is the gradual outcome of his genius.

In answer to the argument that smokeless powder

will operate to increase the percentage of wounded it may be stated that rifles of small calibre are proverbially inaccurate in the mid and remote ranges, and that for this reason a clear field does not offer any marked advantage. The inaccuracy in fire is said to be due to the hygroscopic property of the nitro compounds which compose the new explosives as well as to their poor keeping qualities, both of which cause varying velocities.

It has been proposed to counteract the use of smokeless powder by generating smoke on the field from explosives, chemical substances, etc., in order to conceal the troops from the fire of the enemy, or for any purpose calculated to give advantage in manoeuvring bodies of men. In addition to this, the showy uniform and white tentage heretofore in use are to be discarded for materials with shades bearing but little contrast to those of the field. When the resort to such expedients is considered, in connection with the inaccuracy of the new arm, says Dr. La Garde, it is doubtful if even smokeless powder will have any influence to increase the casualties of battle or to alter the present allotment of relief corps.

The character of wounds inflicted by steel-armored projectiles and the perfect technics in dressing them will have their weight in lessening the work of the sanitary corps in the wars of the future.

The old conoidal leaden bullets of large calibre invariably produced comminution and splintering in the joint ends of bone, and the injuries they were wont to cause in these anatomical parts were attended with marked shock, so that they were always serious at best.

On the other hand, he says, the destructive effects of the jacketed steel bullet in the spongy ends of bone, except at relatively short ranges, are not attended with comminution or fissuring, and the element of shock may be entirely absent or faintly marked. Instead of the enormous destruction of tissues effected by the old leaden bullet, gutting or a complete perforation of the bone without fracture will often be found, and these appearances are specially noted at ranges between three and fifteen hundred yards.

Gunshot injuries of the shafts of the long bones by the old leaden bullet of large calibre were characterized by extensive comminution, isolated fragments free from periosteal attachments, and numerous fissures. On the contrary, the jacketed bullet causes less comminution, the smaller fragments are generally bound to the main fragments by periosteal attachments, the fissures are usually subperiosteal, and the bony lesions have more of the nature of perforations, such as are commonly seen in the joint ends. Complete perforations without fracture are not infrequently seen in the results of the experiments on cadavers and lower animals. Dr. Arnold of the navy, while giving his recent experiences in China in the annual report of his surgeon-general for 1895, details a complete perforation of both femora in the same individual, without fracture, by a steel-armored bullet from a new Mauser. Taking all these facts into consideration Dr. La Garde believes it may be stated without much fear of contradiction that the gunshot injuries of the extremities which have formed such a large percentage of wounds will be less severe in the wars of the future, that the proportion of men in this class who will require transportation to the rear will be smaller than heretofore, and that, therefore, an increase in the number of porters from this source need not be apprehended.

Our present knowledge of treating wounds, he thinks, will operate materially to lessen the burden of the relief corps. In former wars sepsis was the rule in all wounds; the constant attention and frequent dressings entailed a vast amount of work on the medical department of the various hospitals. To-day, when aseptic and antiseptic methods are followed, it is the exception to witness suppuration in wounds; it is seldom that a wound requires to be dressed oftener than once a week; whereas it was necessary in the pre-aseptic era to change the dressings daily and often twice a day. The saving in time, material, and labor is at once apparent when the old methods are contrasted with the new.

#### The Use of Senecio in Disorders of Menstruation.—

In the November number of the *Medical Chronicle* Mr. W. E. Fothergill gives a summary of the work of Dr. William Murrell, Dr. Dalché, Dr. Heim, Dr. Bardet, and Dr. Bolognesi bearing on the therapeutic value of the senecios, and their conclusions as follows:

Murrell, among other remarks, says he found that it succeeded admirably in those cases in which the menstrual function, having been established and performed regularly for some months or even years, was delayed or suspended as the result of exposure to cold or some similar cause. In cases in which the amenorrhœa was associated with or dependent on anemia, senecio uniformly failed to do any good until the anæmic condition had been removed by iron. In cases in which the menstrual flow had never been established, senecio was frequently most useful, and in four cases of vicarious menstruation—the blood coming from the mouth or gums—nothing could have been more satisfactory. He is satisfied that senecio not only anticipates the period, but also increases the quantity. In many cases of dysmenorrhœa it promptly relieves the pain, and not infrequently the headache from which many women suffer at those times. Senecio is apparently not an ecboleic.

Dalché and Heim conclude that the drug relieves painful menstruation if the reproductive organs are healthy, but not otherwise. They remain doubtful whether senecio provokes the menstrual flow, and they offer no hypothesis as to its mode of action.

Bardet and Bolognesi conclude that senesio has the constant property of provoking menstruation, though administered in small and harmless doses. They hold that it always tends to regularize menstruation, but that it does not relieve pain at the periods, and does not increase the quantity of the discharge. They suggest that it both produces congestion of the reproductive organs and also excites contraction of the uterine muscle.

M. Bardet mentioned one of the cases on which the latter supposition is based in a discussion at the Société de thérapeutique. A woman, aged thirty-eight years, suffered from nausea and hypogastric sensations recalling to the mind those of pregnancy, on three occasions after she had taken senecio. But subjective phenomena described by a patient, says the writer, are very slight evidence on which to base a statement, as M. Bardet does, to the effect that her uterus contracted.

M. Blondel thinks that the reports on the physiological action of senecio are both vague and contradictory, and that until the action of a drug is definitely known its indications and contraindications can not be established. Amenorrhœa, he says, is not a disease but a symptom, and its causes must be discovered before they can be attacked. In half the cases seen it was, he said,

due to pregnancy, the diagnosis of which during the early months was beset with difficulties. Therefore he thought the treatment of amenorrhœa should always be indirect, both from the risk of causing abortion, and in order to preserve a true clinical spirit. The drugs which act directly in provoking menstruation, he thought, were unreliable, dangerous, and of merely temporary effect.

Now these remarks of M. Blondel, continues Mr. Fothergill, though likely to catch the sympathy of the superficial reader, are not really calculated to deter any one from giving respectful study to the work of these authors. For, to go over his objections in reversed order, granting that the so-called emmenagogues in use are unsatisfactory, there is no reason *a priori* why it should not be discovered that one or other of the active principles of the senecios is a true emmenagogue, reliable, safe, and perhaps even permanent in its action. Next, in certain cases, amenorrhœa is not a symptom of any pre-existent disease, but is due to the action on the nervous system of various external and temporary causes. Secondary bad effects, both mental and physical, follow the amenorrhœa, which in such cases is a primary disorder, and is certainly one suitable for direct treatment. Thus, Edelheit mentions four cases in which amenorrhœa inaugurated a primary and serious affection, fatal in two of them, recovery in the other two following the re-establishment of menstruation. Again, the difficulties in diagnosing early pregnancy, if great, are not insuperable to all; and there is no necessity for any one to administer a possible ecbole while still in doubt as to the diagnosis. Lastly, if no drug may be used until its action is definitely known and its indications are clearly defined, there is an end to the introduction of new therapeutic agents. All that the most exacting can demand is that the introducer of a new drug shall give a working hypothesis according to which the drug may reasonably be supposed to act.

Menstruation expresses an anabolic surplus produced by the healthy human female from puberty to the menopause, except during pregnancy and lactation, the time of its occurrence probably being determined by the activity of a special centre in the lumbar part of the cord.

Now, says Mr. Fothergill, in the light of this view of menstruation, substances like iron, which affect the quality or quantity of the blood, are only indirectly emmenagogues. Similarly, substances which, by causing renal or gastro-intestinal irritation, promote pelvic congestion and uterine hæmorrhage, are also indirect in their emmenagogue action. To be a direct emmenagogue, a substance must act upon the nervous mechanism which initiates the discharge, namely, the hypothetical centre for menstruation. Thus an emmenagogue is quite distinct from an ecboleic, which is supposed to cause contraction of the uterine muscle by acting either on the fibres themselves or on their motor nerves. It is possible, he thinks, that senecio may be found to contain an active principle which is a direct emmenagogue in the proper sense of the word, and it does not follow that this principle must be an ecboleic.

Several kinds of amenorrhœa, continues the author, may be classified according to treatment, and the indications defined for the use of the direct emmenagogue which senecio may prove to be. From the reports of these authors, it does not seem likely that the drug will be of much use in dysmenorrhœa.

The following is his classification according to treatment:

*No Treatment.*—Physiological amenorrhœa—i. e., before puberty, during pregnancy, during lactation, and after menopause. Amenorrhœa due to congenital or acquired deficiency or to absence of essential reproductive organs.

*Surgical and other Local Treatment.*—Amenorrhœa due to local defects, such as atresia vaginae, atresia cervicis uteri, congenital or acquired neoplasms, etc.

*Indirect Treatment.*—Amenorrhœa due to general disease which so disturbs metabolism that there is no anabolic surplus—e. g., anæmia and phthisis—where menstruation would be an unnecessary drain on the patient.

*Direct Treatment by Emmenagogues.*—Amenorrhœa due to want of activity of the nervous mechanism initiating menstruation, caused by nervous disease, shock (mental or physical), fear or hope of pregnancy, etc., including those cases in which the function has never been established, but where there is no local defect or general disease sufficient to account for its absence.

#### The Action of Influenza on the Female Organism.—

The *Indépendance médicale* for November 25th publishes an abstract of an article by Dr. Gabriel d'Engel (*Wiener medizinische Presse*, October 16, 1896), in which the author states that during the epidemic of 1889 to 1890 influenza occurred as frequently in women as in men; it was also noticed that when the disease attacked a family the women were seized first, but that it was more benign in them than in the men.

In women influenza does not exercise so injurious an action on the respiratory and digestive organs as in men; on the other hand, it produces in them much more frequently disturbances in the physiological functions of the genital organs.

Following the simple disturbances of menstruation there may be observed a series of anomalies of this kind which may resemble an obstruction of the blood or hyperæmia of the genital parts, but which can not be attributed to any other cause but influenza.

The most important pathological alterations are found in the mucous membranes. The genital organs seem to have a special predisposition for the localization of the disease.

In forty per cent. of the cases observed by the author the initial phase of influenza coincided with the menstrual period. The flow of blood was often more abundant and lasted longer than ordinarily. Several of the patients noticed also the presence of clots.

If the disease occurred a week before the regular menstrual period, it provoked menstruation. The author observed that it caused a regular menstruation during several months in anæmic or chlorotic girls, and that in six cases it brought on the first menstruation.

Acute and chronic uterine catarrhs are aggravated by the action of influenza, the secretion becoming more abundant and more like pus.

#### Morphine as an Antidote to Cyanide of Potassium.—

The *Presse médicale* for November 25th states that, in order to kill a dog which had been experimented on several times, Dr. Heim (*Münchener medizinische Wochenschrift*, 1896, No. 37) injected under the skin of the back six grains of morphine, and after a short period of excitation the dog slept. At the end of an hour, however, the dog was still alive and the author, in order

to hasten the animal's death, administered a subcutaneous injection of ten cubic centimetres of a 3.3-per-cent. solution of cyanide of potassium. The effect of this injection, says the author, was altogether surprising; the dog awoke and became very lively. This condition persisted for some time and then the dog was seized with convulsions and died an hour and a half after the injection of the cyanide of potassium.

It is evident, says the writer, that this drug neutralized the effects of the morphine, and that the morphine retarded the toxic action of the cyanide of potassium.

In order to explain this fact, the author made a series of experiments on mice. After establishing the minimum fatal dose of morphine and of the potassium cyanide he proceeded with the experiments, which consisted in treating the animals that had been subjected to injections of potassium cyanide with morphine, and those that had been subjected to fatal doses of morphine with potassium cyanide. With a few exceptions, the animals could always be saved. The morphine seemed to be the antidote to the cyanide of potassium and *vice versa*.

With regard to the mechanism of the neutralization of these two poisons, the author thinks that, owing to the influence of the iron in the blood, which is an alkaline medium, there are formed Prussian blue and an oxide of morphine.

#### The Pine-shaving Cure for Baldness.—

A humorous person recently wrote as follows to *The Sun*:  
"To the Editor of *The Sun*:

"SIR: In answer to your correspondent, J. M., who, in reference to E. S. E.'s pine-shaving and alcohol remedy for baldness published in *The Sun*, asks if it makes any difference what kind of pine shavings is used, I would say that the shavings of almost any of the pine family will answer; but yellow-haired people had better use yellow pine; black-haired, the bull black pine (*Pinus Jeffrego*); true blond, the golden pine, and elderly people the silver pine or the gray pine (*Pinus Banksiana*). In applying the shavings the head should be well pitched and the shavings stuck thereon in artistic festooning. Care should be taken not to strike a match on the head or poke the fire with it while thus treated."

**Adipogen.**—This is a new medicinal preparation made in Norway and patented in the United States. It consists of the salted livers of the cod put up in cans. It is far less unpalatable than cod-liver oil, and the statement is made for it that it has medicinal virtues additional to those of the oil, the tonic properties of the alkalis of the liver.

**The New York Academy of Medicine.**—At the last regular meeting, on Thursday evening, the 17th inst., the following papers were to be read: The Permanganate Treatment of Opium Poisoning, by Dr. William Ovid Moor; and The Essential Nature of Croupous Pneumonia, by Dr. Andrew H. Smith.

At the last meeting of the Section in General Surgery, on Monday evening, the 14th inst., Dr. Willy Meyer was to read a paper on Early Diagnosis and Early Nephrectomy for Tuberculosis of the Kidney. Patients were to be presented by Dr. Willy Meyer, Dr. C. N. Dowd, Dr. R. A. Sands, Dr. John Rogers, Dr. J. P. Tuttle, Dr. Robert Abbe, and Dr. A. L. Fisk.

At the last meeting of the Section in General Medicine, on Tuesday evening, the 15th inst., the following papers were to be read: Mucous Colitis a Functional

Neurosis, by Dr. Walter Mendelson; and Purpura Hæmorrhagica, by Dr. Leonard Weber. A demonstration of instruments of precision used in the observation of cardiac disease was to be given by Dr. H. Newton Heine-man.

At the last meeting of the Section in Orthopaedic Surgery, on Friday evening, the 18th inst., Dr. Leroy W. Hubbard was to read a paper entitled The Prognosis of Hip-joint Disease; patients were to be presented, and new instruments, appliances, etc., were to be exhibited.

At the next meeting of the Section in Ophthalmology and Otology, on Monday evening, the 21st inst., Dr. Ira Van Gieson will read a paper entitled Preliminary Observations on the Cytology of the Cones of the Retina, and Dr. C. H. May will read one on The Optical Society Bill of 1895 to 1896, and its Proposed Re-introduction in the New York Legislature during the Session of 1896 to 1897. Patients will be presented by Dr. H. Knapp, Dr. T. R. Pooley, and others.

At the next meeting of the Section in Laryngology, on Wednesday evening, the 23d inst., Dr. W. C. Phillips will read two papers, one entitled Early Laryngeal Epithelioma, and the other A Point in the Etiology of Chronic Nasopharyngitis. Patients will be presented and new instruments exhibited.

**Laparotomy for Intestinal Perforation in Typhoid Fever.**—The *Gazette hebdomadaire de médecine et de chirurgie* for November 26th publishes an account of a recent meeting of the Société de chirurgie at which M. Monod stated that he had been called to see a man who showed very grave symptoms during the course of typhoid fever which pointed to intestinal perforation. As the general condition of the patient was satisfactory, M. Monod performed laparotomy. The abdomen was filled with serosity, pus, and fecal matter. There was a perforation of the small intestine near the cæcum, which was sutured. On the following day there was very little improvement and the patient died in a few hours. At the autopsy it was seen that the sutures of the intestine had remained in place, but that there had been a generalized adhesive peritonitis.

In the researches undertaken by M. Monod in regard to this subject he had found accounts of thirty-two cases with five recoveries; these cases had been very briefly reported, however, and on a closer investigation the number of recoveries had been found to be two, one reported by Roux and the other by Abbe. In each case the patient had not been operated upon until two days and a half after the onset of the symptoms.

In typhoid fever, said M. Monod, many perforations often occurred in succession, and it had been said that these perforations might be cured spontaneously. Cases had been cited in which this had occurred, but they were exceptional, and in general all cases of perforation ended in death.

He thought the surgeon should operate very soon after the onset of the symptoms when the general condition of the patient was comparatively satisfactory. Median laparotomy should be done and the perforation sutured at a proper distance from Peyer's patches. M. Monod thought that the operation was more successful when the perforation occurred during a relapse of the fever or at the termination of the disease.

M. Rouvier stated that he had operated twelve hours after the onset of the symptoms. He had made a transverse incision near the painful region and sutured the

two perforations which he had found. The patient had lived for ten days and died after two other operations had been done.

**The Best Treatment of Scabies.**—The *Province médicale* for November 21st contains an abstract of an article from the *France médicale* for October 30th, in which the author, M. Julien, states that he has treated a great number of women by painting the entire body with the balsam of Peru, which exercises a toxic action on the acarus. The application of this remedy is very simple. No soap and water should be used before its application, for the greasy substances of the body, he says, are very useful in promoting the action of the remedy. With a brush a thin layer of the balsam is laid on the body and then rubbed in gently. The volatile properties of this agent enable it to penetrate the furrows easily, thus rendering it unnecessary to tear them apart; afterward a cleansing bath is given. In order to obtain the best results, M. Julien recommends practising the paintings at night and resort to the bath on the following morning, so that the patients may receive the full benefit of the agreeable exhalation, which resembles that of benzoin; this condition, however, he says, is not indispensable. If the disease is of long duration there will be no inconvenience in prolonging the action of the remedy, as it causes no irritation and is always well borne.

M. Julien states that he has employed the balsam systematically for a period of five years, and that it has shown itself efficacious in all cases, even in those of long standing and in those in which grave relapses have occurred. He thinks that this remedy is clearly indicated in subjects suffering from impetigo, ecthyma, eczema, cardiac troubles, albuminuria, etc., during menstruation, in certain pregnant women, and in all other subjects for whom baths are interdicted. He recommends it also for nurslings.

In a word, he says, it is a simple measure which any patient may easily apply himself, its action is very certain and exact, and it has a pleasant odor which is especially appreciated by patients.

M. Julien says that he does not know of any contraindication to the use of this agent, and, he adds, the same can not be said of the ointments which contain sulphur, for their most ardent advocates have been forced to acknowledge that there are many contraindications to their employment.

### Three Cases of Subcutaneous Emphysema in a Family.

—At a recent meeting of the Société médicale des hôpitaux, a report of which is published in the *Journal des praticiens* for November 25th, M. Galliard stated that M. Valdés, of Matanzas, Cuba, had reported three cases of subcutaneous emphysema complicating measles. Two of the patients had been observed by himself, and he had found that in one patient the emphysema extended from the neck on both sides to the trunk and to the left arm; in the other patient it was limited to the neck. In both cases there was slight bronchitis. The third patient had died six days later, of pulmonary tuberculosis. The two brothers of these three patients did not present any similar symptoms. All five had had whooping-cough without any complications. Their father was asthmatic.

M. Galliard thought that there was a congenital weakness of the pulmonary vesicles and also a predisposition produced by the whooping-cough.

## Original Communications.

## A STUDY OF IRRUPTION OF THE TEETH INTO THE NASAL CHAMBERS.

A RÉSUMÉ OF REPORTED CASES  
AND A REPORT OF ADDITIONAL CASES.\*By ALEXANDER W. MACCOY, M. D.,  
PHILADELPHIA.

In the study of the irruption of teeth in the nasal chambers undertaken in this paper, the writer had not proceeded far into the subject before he found that valuable contributions to the literature were already on record by several members of this society. In the attempt to make a complete *résumé* of the subject, some difficulties have presented themselves by reason of lack of completeness in histories and absence of definite details in some of the papers; also by reason of inaccessibility of some of the journals in which the original papers appeared. Two supplementary histories have been added in this paper—one, that of Dr. Arthur W. Watson, of Philadelphia; the other, my own. In some of these cases marvelous energy in the attempt of the tissues to get rid of the foreign body was shown, and years elapsed in the accomplishment of it. In one instance this irruption was dependent upon violence directly applied, and might be considered as fully expressing the root meaning of the word "irruption." All cases in which both the irruption of the tooth and its removal have not occurred in the nasal chambers have been excluded from this paper. Very many interesting cases of irruption of teeth into the antral cavities, and formation of dentigerous cysts in the orbital cavities, etc., are found in literature, but are excluded by this limitation. I shall hope to take up the antral cases in a later paper.

I submit condensed histories of the following cases: Zuckerkandl (*E.*), vol. i, chapter xv, page 551.—It has been observed that incisor teeth sometimes develop in the floor of the nose, their crowns pushing into the anterior part of the nasal fossa. This anomaly is only possible by supposing a rotation of 180° of the dental germ. The enamel, instead of growing downward, directs itself toward the nasal fossa. Under these circumstances the tooth is inverted and the crown penetrates the nasal fossa. Salter, quoted by Sternberg, has seen a dental germ completely inverted in such a manner that the crown was in the place of the root. (*Handbuch der Zahnheilkunde*, edited by J. Scheff). He gave to this anomaly the name "inversion." These inverted teeth were always superior incisors, according to Salter, and one could see the crowns in the nostrils, through which one is obliged to extract the teeth. A

very interesting case of this kind (anomaly of median incisor) is represented in Plate LIII, Figs. 3 and 4. In this is seen a peg tooth, fourteen millimetres long, completely inverted obliquely between the suture of the two maxillary bones, the crown protruding in the left nasal fossa. This is not a supernumerary tooth, but a rudimentary median incisor transposed from the right side. The right alveolar apophysis is contracted to the size of the average incisive alveolus. The lateral incisor is advanced toward the median line. The maxillary framework was remarkable for anomalous development; also, the nasal bones were absent. In the same paper Zuckerkandl quotes a canine tooth as occurring in the nasal fossa, reported in the *Correspondenzblatt für Zahnärzte*, vol. xii, Berlin, 1883.

It was the case of a man who had suffered for a long time from obstruction of the nasal fossa. At the distance of two centimetres and a half behind the orifice of the nostril a movable canine was found and was easily extracted. Zuckerkandl also relates another case coming under his own observation of a premolar in the nasal fossa, of which the following is the description: At an autopsy, examining the nasal fossa, he struck something hard in the inferior meatus; the surface of it was covered with a mass of pus; it crossed the lower border of the turbinated and approached the wall. All around it the mucous membrane was swollen and injected, and in places showed purulent infiltration; he believed it a case of rhinolith about a foreign body. After cleansing, he saw the crown of a tooth which had irrupted obliquely across the maxillary wall. This is the description: Left nasal fossa, mucous membrane relatively normal except for tumefaction in the neighborhood of the tooth; the mucous membrane was thinned by the pressure of the mass. The tooth was found in the inferior meatus two centimetres behind the pyriform opening. It was twenty-five millimetres long, eleven millimetres of it situated in the nasal fossa. The crown was seven millimetres long. There was a space of about three millimetres between the base of the tooth and the nasal floor. The mucous membrane of the lateral wall of the inferior meatus presents a depression for the tooth, the border of it pressing against the root of the tooth. The neighboring bone to the tooth is carious on account of the molar roots. He reports the teeth of the superior maxilla to be irregular in development, there being only two incisors, a canine, and the first premolar. The others are missing. In their place the alveolar process is atrophied, and forms a large, thick lump. The left superior maxilla shows great irregularity in the position of the teeth; the left canine is not irrupted; of the premolars, one is missing. The crown of the first premolar is found in the nasal fossa with a part of the root, about twelve millimetres in length, projecting into the facial wall of the maxillary. The abnormal tooth occupies such a position that it is turned 90° toward the median line.

Roy (*Gopard Chunder*).—Roy, of the Sooree Charitable Hospital, reports a case of a Hindu boy, aged fourteen years, who presented himself for treatment for what he considered a tumor growing in his nose. For four months he had had a fetid catarrh with occasional epistaxis. For the previous two months the growth had been observed occupying the

\* Read before the American Laryngological Association at its eighteenth annual congress.

left nasal cavity, where it seemed to be attached to its wall at its upper part, its free end looking downward in the shape of a truncated cone. The tumor was seized with dressing forceps and extracted. It proved to be a canine tooth. The free extremity was covered with enamel, which stopped short at its junction with the root. The root was deeply imbedded in the side and upper part of the antrum. The boy had got his set of permanent teeth with the canines and incisors on both sides. There was no deformity of the jaw, and no swelling or cystic formation. It was clearly a case of extrafollicular development and irruption of a tooth in the wrong place, the peculiarity being that while in reported cases of a like nature the crown of the tooth shows itself at the floor of the nasal cavity from below upward, in the present instance the dental follicle was transposed, and the irruption was from above downward. The tooth is in the English Royal College of Surgeons Museum.

*Hall, De Haviland.*—Hall reports a case of a girl, aged fifteen years, in whom there existed in the right nostril a misplaced tooth, which proved to be the right permanent canine. There were marked signs of hereditary syphilis, and a fetid discharge issued from the nostrils; the nasal septum was also perforated. The tooth was extracted from its abnormal position three months after it was first seen.

*Schaeffer, Max, of Bremen.*—A case is reported by Schaeffer of a man, aged thirty-six years, who for a long time had suffered from obstruction of his left nostril. Since the age of fourteen he could feel a hard body in the left nostril with his finger. All his teeth were present in their normal position. The foreign body was extracted with a snare and forceps and found to be an incisor, measuring in length a centimetre and a half; in its greatest breadth, half a centimetre. It had for its crown enamel. On its small root it had a little cap of cartilage.

*Ingals, E. F., Chicago.*—In examining a patient who had for some time suffered from nasal catarrh, Ingals found on the floor of the left naris, four centimetres back from the nostril, a hard substance, feeling, when touched with the probe, like bone. On seizing it with forceps, the patient suffered severe pain like that caused by striking a decayed tooth. The pain was so intense that it was necessary to anesthetize the patient before a thorough examination could be made. After the patient was etherized, the body was engaged in a snare and drawn out, when it was found to be a supernumerary tooth, resembling closely a canine, and two centimetres in length. About five millimetres of the tip of the root had been exposed in the nasal cavity, and below this the tooth was covered with soft tissue which was adherent to it down to the crown. The dentine of the crown was perfect, excepting a small perforation at its apex, but within the tooth was decayed. The tooth must have been projecting within the nasal cavity for some time, for the portion of the apex of the root which was uncovered had lost by erosion about a millimetre in thickness from its entire circumference. He says: "It is comparatively rare for teeth to grow in the roof of the mouth or nasal cavities, yet several such cases have been met with. In nearly all instances the 'wild tooth,' as it is called by the laity, is found to be a supernumerary tooth or a misplaced canine." Professor E. S. Talbot examined the tooth and the patient's mouth, and stated that from the appearance of the tartar and green stain upon the

apex of the crown it must have occupied a diagonal position in the hard palate, the crown being in the roof of the mouth pointing toward the central incisors and the apex of the root in the naris pointing posteriorly. A ring of tartar encircled the crown from about three millimetres below the upper surface to nine millimetres above the lower surface, and that part of the crown below the ring was covered with a fungous growth, which proved that that part only was exposed in the mouth. The tooth had decayed because of the imperfectly formed apex of the crown until the pulp had become exposed, and death had resulted, causing alveolar abscess, the sac of which came away with the tooth. He concludes: "While it is not uncommon to find supernumerary teeth in the roof and anterior part of the mouth, it is very rare to find the apex penetrating the nares."

*Marshall, J. S., of Chicago,* reports a case of a superior wisdom tooth discharged from the nasal passages. A woman, aged sixty-two years, had suffered from facial neuralgia on the right side accompanied by severe otalgia for ten years. In October, 1884, she suffered intensely from what she supposed to be a "severe cold in the head." The right nostril became slightly swollen and completely obstructed. Breathing was almost impossible when the lips were closed. After an unusually great effort in coughing and blowing her nose, a few days after the onset of the cold, she suddenly felt something fall upon her tongue which proved, upon examination, to be a large, right superior wisdom tooth, covered with fetid pus. There was immediate relief of facial pain. Thirty years previous she had all her upper teeth removed. About four years after the removal of her teeth a tumefaction appeared upon the right superior maxilla, near the tuberosity. She consulted a dentist, but he could offer no explanation of the swelling, which disappeared in a few days. In May, 1884, she suffered from an abscess of the right ear. For several years previous to the discharge of the tooth she had had a slight fetid discharge from the nose. Dr. Marshall offers the following explanation of the symptoms: That all the pain and discomfort in the right facial region were due to this erratic tooth. The pain and swelling twenty-five years previous to the discharge of the tooth were due to the irruption of this tooth in an inverted position, which, taking a direction upward and forward, finally pierced the floor of the antrum of Eilghmore. The abscess in the ear must have been the result of an abscess at the roots of this tooth, which discharged its contents into the meatus and at the same time freed the tooth from its crypt and left it loose in the antrum. The tooth finally worked its way to the anterior portion of the antrum, and, by contact with the nasal wall, produced ulceration of this and of the inferior turbinated bone, and thus found its way into the nasal passages. The catarrhal discharge was due to the presence of the tooth in the antrum. Dr. Marshall regards the case as interesting in that it explains an obstinate case of trifacial neuralgia and indicates the probable cause of a severe aural abscess.

*Griffin, E. Harrison, of New York.*—Dr. Griffin reports a case observed at the Bellevue Throat Clinic. A male, aged thirty-two years, complained of sore throat of two days' duration. An examination of his throat showed a cleft of both the hard and soft palates. In examining the upper gum Dr. Griffin noticed the root of the second incisor tooth in the tissue, and an examination of the nose showed the tooth in a perfect state of

development projecting from the floor of the nostril up into the nasal cavity. He said the tooth had been there for years and gave him no trouble. He never suffered any pain when it was growing, and did not know it was there until one day when, inserting his finger into his nose, he noticed something hard, and looking into a mirror found it to be the tooth. As it gave him no trouble he did not go to a doctor. He did not think the tooth had grown any of late years. The patient was opposed to any operation for the removal of the tooth.

*Wright, Jonathan*, of Brooklyn.—Dr. Wright mentions six cases, all of which are reported in this paper. In all the cases reported the teeth were anterior ones, canines or incisors. He adds: "The reasons are obvious, since the posterior ones, if inverted, as in Griffin's case, would grow into the antrum." He says the first of his cases is interesting as illustrating the migration of an object through bony structure, while the second case was evidently originally one of extra-alveolar development.

**CASE I.**—A woman, aged thirty-five years. Four years previously she had had all her remaining teeth, nine in number, extracted from the upper jaw. The dentist told her he thought he had left a piece of a lateral canine or incisor on the left side. For some time before Dr. Wright saw her she had suffered from nasal obstruction on the left side. An intranasal examination showed marked hypertrophy of the nasal mucous membrane on the left side. A probe detected a rough, hard surface about half an inch from the left anterior meatus, on the floor of the nose and close to the septum. Small pieces of calcareous matter or bone could be crumbled off with the probe. Two weeks later the patient brought to the dispensary a small sequestrum which she had washed out herself. By means of a probe and forceps, he then extracted the single root of a tooth, about three quarters of an inch long, from the left nostril.

**CASE II.**—A girl, aged eight years, had suffered from nasal obstruction since she was a year old. There had been considerable offensive discharge. The bridge of the nose was sunken, the nostrils were flattened and contracted. The superior alveolar process on the left side corresponding to the situation of the canine and incisor teeth was absent, leaving a slight cleft. There was no history of accident. The left nostril was obstructed by a foreign body which grated under the probe. Considerable force was required to extract it. It was found to be the crown of an incisor tooth. It was notched, as in young children, and larger than in a child a year old. There was considerable calcareous matter around it and in the nostril, but no root was found.

*Thompson, J. A.*, Cincinnati.—At a meeting of the Cincinnati Medical Society, Dr. Thompson presented a specimen of a "tooth and portion of socket taken from the middle meatus of the nose."

A girl, aged eighteen years, came to the Nose and Throat Clinic in 1890. She had been in good health until vaccinated at the age of five years. Vaccination made her very ill; an eruption appeared on all parts of her body; her eyes became affected and she was completely blind for a time. At the age of eleven she began to complain that her right nostril was obstructed. An eruption again appeared, and the glands in her neck became swollen. She was under treatment for about two years at that time, without much improvement.

Mercurials must have been freely given her, for she was badly salivated. Since the right nostril was occluded—seven years ago—she has had neuralgia on the affected side. The breath has been extremely offensive for three years. Four years ago, at a clinic in Pittsburgh, dead bone was discovered in the nostril. An attempt to remove it at that time failed. Examination revealed that both corneæ were clouded by linear opacities and maculae. In both eyes the iris was fixed by posterior synechiae. The uvula and part of the soft palate had been destroyed. The tonsils and pillars of the fauces showed numerous cicatrices of old ulcers. In the nose, the septum was much deflected to the left. In the right nostril a white substance was seen in the middle meatus. It looked like a tooth lying horizontally in the nostril with the crown forward. Its attachment was concealed by exuberant granulations, such as always spring up around dead bone in the nose. It could be easily rotated up and down by grasping it with dressing forceps, but could not be dislodged even with strong polypus forceps. With a pair of strong sequestrum forceps he dislodged it and brought it forward to the nostril. It was seen to be the right lateral incisor tooth, with its root in a socket, and surrounded by a mass of necrosed bone. The mass was so large it could not be extracted through the nostril. He pulled the tooth from its socket, then broke the bone in small pieces with the forceps, and removed the whole thing. In the discussion following the report of this case, Dr. M. H. Fletcher expressed the opinion that the case was probably one of displacement of the intermaxillary (or incisive) bone during development. This seemed very plausible, since persistence, either partial or complete, of the premaxillary suture is not rare, even in our own race, and is frequently seen in some of the lower races, such as the North American Indian. Dr. Joseph Eichberg thought that if a portion of the maxilla had become necrosed from mercurial stomatitis, the tooth could have been lifted into the middle meatus of the nose by the subsequent process of granulation.

*Kayser, R.*—Dr. Kayser reports a case of a tooth removed from the left nostril of a girl, aged fifteen years, who for more than a year had had profuse discharge from the nose, and the nose was also much obstructed. Examination revealed swelling of the mucous membrane with exuberant granulations in the left nostril and the probe touched roughened bone. Behind this was a whitish body which, on being removed, proved to be a much incrustated infantile incisor tooth. It is probable that the tooth had acted as a foreign body for nearly a year.

*Knapp, H.*—Dr. Knapp reports that a healthy-looking boy, aged seven years, came to his clinic with necrotic rhinitis and acute purulent otitis on the left side, and an hypertrophied tonsil on the right side. The lower passage of his left nostril was filled with mucopus and decaying soft and hard masses of tissue. On removing all the dead material from the nostril, he remarks that among the sequestra two were conspicuous—the one, flat and hard, was removed from the lateral side of the floor of the nostril bordering the malar antrum; the other, from the anterior part, was cancellous, and inclosed a tooth, the crown of which appeared to be turned up and back. The sequestrum was fifteen millimetres long and represented a piece of the upper jaw, the rounded alveolar surfaces separated by a layer of cancellous bone three fifths of a millimetre thick. The tooth was the lateral incisor, its crown

healthy and well formed, twelve millimetres long and eight millimetres broad. Its root was decayed. Between the first incisor and the canine a probe could be passed through a rough-walled canal from the mouth into the nose, its direction being toward the nasal septum. Dr. Knapp mentions the fact that Zuckerkandl and Salter have both noticed such inversions at the upper incisors, the crowns of which appeared in the nostrils, out of which they had to be extracted. It might be supposed that the tooth was in its proper position, and was carried up into the nostril with the sequestrum from the alveolar process of the maxillary bone. He concludes: "Be this as it may, the above communication records an example of necrosis of the floor of the nose, and the removal of a loose sequestrum with the corresponding incisor tooth through the anterior naris. That an inverted tooth projecting over the floor of the nose should produce caries or necrosis of its alveolar walls seems very natural if we think how easily the nasal secretion retained by the tooth may decay and infect the bed and the crown of the tooth."

*Schötz.*—At a meeting of the Berlin Laryngological Society, Dr. Schötz showed a case of a tooth in the right nostril of a man, aged nineteen years. It was in the floor, two centimetres from the entrance to the nose. The point stuck up through swollen mucous membrane. It was removed with ease by means of an ear spoon, and proved to be an incisor tooth. The man's dentition was normal, except that a back tooth on the right side was missing, so that this was not an inverted but a supernumerary tooth.

*Harrell, R. F.,* Ruston, La.—A man, aged thirty-four years, came to Dr. Harrell for treatment for nasal catarrh. For six years he had suffered from this catarrh and from the most severe pain throughout the right side of his face. Breath very offensive. Upon examination a large white substance was discovered springing from the floor of the right nostril, about an inch from the meatus, and almost filling the nostril. It was hard and firmly fixed. He broke it from its attachment with strong forceps. It proved to be a perfect tooth, similar in shape to a canine, but somewhat smaller. The mucous membrane was adherent to the tooth in a similar manner to that in the alveolar process. The catarrhal symptoms all ceased.

*Joachim, O.,* of New Orleans.—Dr. Joachim's case was under treatment for specific ulceration of the nasal septum a year previous to the visits reported here. The removal of some sequestra and a course of specific treatment brought about a cessation of symptoms at that time, and the patient returned for observation because of a continuous profuse discharge from his right nostril. The discharge was not purulent. There was a prominent elevation from the floor of the nose. On examination with a probe from behind forward a very rough surface could be felt. He pried it from its bed with a strong dental hook. It proved to be an incisor tooth. There was no tooth missing, and no irregularity in the growth of the teeth of the patient; therefore he looked upon it as a superfluous, not an inverted tooth. Its location was an inch and a third from the bony margin of the nose, and two inches and a half from the tip of the nose.

*Seifert* (*Privat-docent* at Wurzburg).—After a review of the literature he is able to find on the subject, Dr. Seifert reports the following case: A man, aged twenty-five years, was sent from the Polyclinic for Diseases of the Ear with the note that the right nostril was com-

pletely occluded. Examination showed on the floor of the right nostril, about two centimetres from the entrance of the nose, a foreign body, hard and white, lodged in a mass of granulation tissue which extended a little over it. Having lifted the granulation tissue by means of an *écraseur*, the foreign body could be pushed backward and extracted through the posterior nares. It could not be determined with certainty in what manner it had become fixed in the nose. Exploration with the sound revealed no roughened bone or fissure. It was recognized as a tap-rooted or pivoted tooth, which was partly incrustated with calcareous salt. The dentition was complete, the teeth well formed and without other anomaly. The upper jaw was also normal in conformation. Patient had not had any suspicion of the presence of a foreign body in his nose. In this case, as in that of Daas, there had occurred an invagination of the dental germ into the nasal mucous membrane.

*Brindel, A.*—Dr. Brindel, under the heading *A Tooth Implanted at the Entrance of the Right Nasal Fossa, with Reflex Troubles* (Accession of Cough and Laryngeal Spasms), reports the following case: Mrs. B., a servant, aged sixty-two years, consulted Mr. Moure at the clinic for diseases of the nose, larynx, and ears. She complained, not of the presence of a foreign body in the nose, for of that she was unconscious, but of accessions of cough and spasms of the larynx coming on at irregular intervals. She had at times three or four accessions in the same day, on other days none. Twice the spasms had been sufficiently severe to produce syncope. This had gone on for five years. For a long time she had had a tooth abscess on the right upper jaw, opening into the buccal cavity, but of which she could give us only very vague accounts. On account of the cough and laryngeal spasm, Mr. Moure thought there must be a question of reflex trouble from the nasal pharyngeal or laryngeal point of departure. The pharynx and larynx showed nothing abnormal, but at the entrance of the right nasal fossa could be seen a white, round body covered with mucus, having the form of a tooth and imparting to the probe the feeling of bone. It was, in fact, a tooth implanted in the floor of the nasal fossa, which emerged for about half a centimetre from the mucous membrane. It was covered with enamel which was notched. The upper part, concave and rugose, gave exactly the appearance of a carious tooth. One could impart slight lateral movement to the tooth. The upper jaw, very well formed, had not had since the age of twenty-eight years either incisors, canines, or little molars on the right side, but she said she had had a normal dentition and the teeth had been well placed, decaying very early. The tooth was extracted with an ordinary forceps. Extraction was easy and not attended by the loss of much blood. It had the root implanted in the superior maxilla, pointing from above downward—in the opposite way, consequently, from normal teeth. An interesting fact is that the patient has not had the least accession of suffocation since the day when the supernumerary tooth was removed.

*Watson, A. W.,* Philadelphia.—Written communication of an unpublished case from Dr. Arthur W. Watson, of Philadelphia.

"The case was of a man, thirty-three years of age, who had a sarcoma of the right nasal chamber, involving primarily the inferior turbinate bone—subsequently the whole superior maxilla. During an attempt, under ether, to remove the diseased tissue, the instru-

ment struck a hard substance imbedded in the tissues under the inferior turbinate bone. On removal, this proved to be the root, or part of the root, of a tooth.\*

Graham, George W., Charlotte, North Carolina.—A child, female, aged ten years, was brought to Dr. Graham for treatment for nasal catarrh. Eighteen months previously the child had run against the iron hinge of a gate and knocked out one of her front teeth—the right central incisor—and otherwise injured her mouth, which bled profusely. An examination of the nose showed the left nostril normal, the right nostril filled with a polypoid growth from beneath which there oozed constantly a watery fluid. After removing the excrescence, the tooth which had disappeared was discovered firmly imbedded in the inferior turbinate bone; the crown presented to the front. The girl had struck the hinge with such force as to drive the tooth entirely through the superior maxilla and bury it in the nasal bone, and so thoroughly had it united with the parts that it was impossible to remove it with forceps without doing further injury to the nose. With the assistance of Charles L. Alexander, dentist, the tooth was soon severed from its connections. The patient had a perfectly normal condition of the remaining teeth.

MacCoy, Alexander W., Philadelphia.—Anna S., of New Jersey, white, aged forty-five years, came under my care having the following history. Family history shows phthisis and eczema. Personal history: Has always been delicate. Shortly after birth she had a gathering just beneath the right orbit, which opened and remained a suppurating sore for several years. There was extensive necrosis of the bones of the face on that side. This finally healed after the condition had lasted for several years. The depression resulting from the loss of bone can be seen and felt. She was born at full term. At time of birth she had two teeth on the right side of the upper jaw just behind where the eyetooth normally is. These were pulled by the doctor in charge a short time after birth. Her primary dentition was normal, all the teeth coming through except the one just back of the right eyetooth. These teeth, which she got when a child, remained permanently, and she never had a second dentition. Her teeth were always bad, and she suffered so much from them that in 1884 she had them extracted, and has since worn artificial teeth. Ever since she can remember she had catarrh of the right nostril. Very offensive discharge. Occasionally small pieces of bone came away in the discharge, the size of finger nails, black and ragged and felt gritty. In 1884 she sought relief at a dispensary. At that time she could feel a gritty substance beneath her right orbit, as though there was a piece of loose bone there. She could also feel a hard substance in her nose by inserting her finger. She continued going at more or less frequent intervals to the dispensary. In September and October, 1895, she suffered so intensely from occipital and temporal headache that in the first week of October she went to the Out-patient Department of the Pennsylvania Hospital, where she first came under my care.

Inspection of the right nasal chamber showed a pinkish-white glistening object on the floor of the nasal fossa, which appeared to project from it, and resembled a polypus in color. Examination by probe revealed hardness, fixation, and sensation of bone, and the object was dignified a tooth—root presenting. The distance from the vestibular opening was four centimetres; the visible projecting root one centimetre in length, directed at a slightly oblique angle

toward the median line and free from contact with the nasal chamber. The right nasal cavity was markedly irregular, the anterior portion of the lower turbinate bone being rudimentary. The surface of the floor of the nose was very irregular, with marked deflection of the nasal septum to the left. Great hyperæmia of the mucous membrane existed.

The removal of the tooth was accomplished without much difficulty by the use of long, narrow sequestrum forceps. Upon its removal the hæmorrhage was free, followed some hours later by secondary hæmorrhage. No necrosis of the surrounding bony tissue was observed. After rapid healing, a depression remained in the floor of the nose where the tooth had been. The occipital and temporal pain was markedly relieved, and the local and general condition greatly improved. Examination showed the tooth to be a permanent bicuspoid.\*

## THE EARLY RECOGNITION OF UTERINE CANCER,

WITH SOME REMARKS ON ITS TREATMENT.\*

By D. ERNEST WALKER, M.D.

WITHIN the last few years the importance of this subject has been more and more impressed upon my mind, and, while I shall not offer anything new as to the symptoms or treatment of this dread disease, I believe that these symptoms and the importance of their early recognition should be repeated and repeated and repeated, until they can not be overlooked nor forgotten.

Coming in contact with many cases of this disease, both in early and in advanced stages, I have noted time and again the woeful carelessness of medical attendants to whose notice these symptoms had been brought. I say carelessness, because after all that has been written and rewritten on the subject of uterine cancer, I can not believe that any man of ordinary intelligence who reads can be ignorant of the symptoms and signs of this disease when they are plain and unmistakable. I believe, therefore, that repetition again and again is the only way in which to impress the importance of early symptoms of this disease upon the profession at large. And upon its early recognition depends the only hope of successful treatment. The observation of symptoms pointing to cancer depends, as a general rule, upon the family physician, the successful treatment in most cases upon the specialist, and the recognition of symptoms of the disease in its early stages is of as much importance to the one as to the other.

But a few days ago I took the histories of two women with cancer of the uterus too far advanced for any except palliative treatment. Both of these women had danger signals pointing to cancer of the uterus for months and had consulted their physicians about these symptoms. In both instances the trouble had been ascribed to the menopause, and no examination had been made until too late. The histories I obtained from these women did not lead me to believe that either of their physicians were ignorant men or that either failed to suspect the true state of affairs; yet both pa-

tients were allowed to go on for months with the old threadbare explanation of the menopause to account for every symptom until the last hope of successful treatment was gone. To make matters worse still, each case gave a family history of cancer.

Now what is the explanation of this? How is it that an educated physician within twenty-five miles of New York—yes, even under the shadow of the Academy of Medicine—can attribute frequent and increasing uterine hæmorrhages, sanious and watery discharges, and progressive anæmia, sometimes accompanied with pelvic pain, to the menopause, and make no examination, though consulted again and again? Is it ignorance? In this age of societies, books, and journals one can scarcely think so. Yet if this be true in some instances, the early signs and symptoms of cancer of the uterus must be repeated until, like the child's *a, b, c's*, they must be recognized. How is it that the hæmorrhages must even become fetid before some physicians seem to suspect or wake up from ergot, styptics, etc., to the fact that something must be done—when nothing can be done? Is it because of the fear of losing fees or that other men may get the patient? A greater mistake is never made, for if perchance, as often happens, the patient finds there has been a failure to recognize so serious a trouble until too late, and that valuable time has been lost, not only the patient and her family, but often all their friends, seek other advice and spread their story far and wide.

How is it that a physician does not discover that a case is beyond all chance of benefit from his treatment until it is beyond the skill of any one? Is it because he considers cancer of the uterus incurable—that it is sure death any way, and therefore unworthy of his best effort? He should read and he will find that statistics show a large percentage of permanent recoveries from early removals. While all these things may play some part, I believe that most of the failures to make an early diagnosis of this disease, when it presents symptoms, is due to carelessness. How prone one is to say to himself when consulted with reference to some of these symptoms, which at first appear trivial: "Oh, this woman can't have cancer—I know all the family and there is no history of cancer in it. It is not convenient to examine her now, and besides, it is only the menopause causing a little disturbance. I don't want to frighten her by treating the matter seriously, and it must be all right." So you prescribe something, and ascribe the symptoms to the menopause—remarking that when that is over she will be well. This, to her, explains every ill, for she has from her youth heard stories concerning the change of life and is prepared to expect anything. So she goes away and the symptoms continue, but as she does not suffer she does not consider it necessary to consult you again. Then you begin to think your lingering fear of cancer in her case was groundless, as you hoped it was, and you get rid of your twinges of conscience. About the time your last twinge is gone you

\* Read before the Society of the Alumni of the City (Charity) Hospital, October 14, 1896.

see her somewhere and notice she has grown pale. She tells you that the symptoms she had before have continued and of late have grown worse; that she also suffers sometimes now from pain. On examination you find a large growth involving not only the cervix but the vaginal wall, or a tumor of the body of the uterus with fixation, or some other equally serious condition of a like nature. This, I believe, often accounts for a failure to make an early diagnosis. We fight against our own conviction of the truth, and, knowing that we may be mistaken in suspecting cancer, we hope we are, and temporize with danger instead of sifting the matter at once. We dillydally and talk of the menopause instead of regarding these signals of danger as something which, if properly heeded, will save our patient from disaster.

If we suspect a woman has cancer, is it just and right to conceal the suspicion in our own bosoms when to her it is a matter of life or death? Is it not our bounden duty to use every means in our power to decide the question, laying the facts before some member of her family, or, if need be, before the woman herself? I fear that we go too far in the concealment of danger from the victim. Is it not analogous to allowing an individual to walk unwarned across a bridge which is sure to fall and engulf him? Do we not sometimes sacrifice duty and the lives of others rather than place ourselves in a disagreeable position? It is so much easier to let things glide along, and in the end our fears may prove, as we wish them to be, groundless.

I shall not go into the pathology of uterine cancer nor into a description of its different varieties, but shall merely mention its most prominent symptoms, the early signs of its presence, which are so often unheeded. These symptoms are practically the same in all varieties. Unfortunately, however, some cases do not present early symptoms, or, if they do, medical advice is not sought. With these this paper has nothing to do. The trouble is not that the symptoms are unknown, but that they are unheeded—so I shall not go deeply into symptomatology. This is more thoroughly treated in text-books than could possibly be done in the limits of this paper.

The most prominent symptom is hæmorrhage of an irregular character, both as to time and quantity, occurring usually about the menopause—an increase in quantity, and, perhaps, irregularity, if the menopause has not occurred; and a return of hæmorrhagic flow if that period is past. Later, there is generally a watery discharge, sometimes of a bloody, serous character. Sometimes the first symptom is hæmorrhage after coition. Any moderately profuse vaginal discharge occurring about the menopause, no matter what its character, should excite suspicion, and an examination should be made. The hæmorrhages may often be mere stains on the linen. When a small tumor, which you know a woman to have and which has caused no previous trouble, begins to enlarge and is attended with pain or hæmorrhage, it

becomes very suspicious, and so does any new growth or hardening of the cervix uteri which you observe. Pain is rarely a symptom early in this disease.

Given a case of suspicious symptoms in a woman, especially about or following the menopause, our first duty is to make a thorough examination. If there is any enlargement of the cervix or body of the uterus, a hardened or patulous condition of the cervix, or any growth or ulceration in or upon it, the suspicion should be considered confirmed until it is disproved; for this is a case where it is proper to consider one guilty, so to speak, until he is proved innocent. This can be done only by microscopic examination of pieces cut from the cervix, or scrapings taken from the endometrium with a sharp steel curette, or both. The pieces should be cut as deeply as possible from the cervix, and the curetting should be very thoroughly done. The specimens should then be sent to some reliable pathologist, and if the report is unfavorable, you are brought to the consideration of the treatment that offers your patient most chances of permanent cure. It is, I believe, to-day an almost undisputed fact with the profession that total extirpation of the uterus and its appendages offers by far the best chance of a permanent cure, always bearing in mind that the ultimate success of the operation depends upon its being done before the disease has extended beyond the tissues of the uterus proper, before fixation occurs, and before it has involved the vaginal wall or infiltrated any of the adjoining structures. When thus done, the percentage of ultimate recoveries is very good. Hofmeier has reported thirty-three per cent. after four years; Fritsch, thirty-six per cent. after five years; Schauta, of Prague, 47.3 per cent. after two years; Olshausen, 47.5 per cent. after two years; the Dresden Klinik, 58.4 per cent. after two years; and Leopold, seventy-two out of seventy-six patients still well and with no return after five years and a half.

Not only does early operation offer these advantages, but it is free from one great objection to all other methods of treatment so far tried—namely, its performance does not preclude the trial of other measures. In those cases which it does not permanently cure it prolongs life—unless, as is rarely the case, the patient dies of the immediate effects of the operation. Therefore, a better chance is offered for the effect of any internal treatment, such as thyroid or other glandular extracts or toxins. If these are ever effective, as is claimed, in large or advanced cancerous masses, they should prove much more speedily so in small ones, or in those tissues which are just taking on a cancerous condition. Thus, early operation would prove an aid rather than a detriment to their use, and consequently should not be opposed by the most skeptical. On the other hand, the same can not be said of the use of internal remedies and local applications, since they cause delays which are fatal to successful operation.

Apparently the chances of a complete cure from

operation are much better in those who are attacked with cancer of the uterus during or after the menopause than in those who have it before that period. This is probably explained by the fact that the generative organs are in a much more active state before than after the menopause, when atrophic changes begin, and the adjacent structures being also more active and full of blood are more easily and rapidly invaded.

In conclusion, I would suggest that the profession attempt in every way to eradicate from the mind of the laity the idea that the menopause is a sufficient explanation of every symptom affecting the female pelvic organs at or about that period; just as they are gradually getting rid of the old and pernicious belief that "catching cold" is responsible for puerperal fever and other septic troubles.

219 WEST FORTY-THIRD STREET.

## URIC ACID AS A FACTOR IN THE PRODUCTION OF HAY FEVER.\*

By NORTON L. WILSON, M. D.,

ELIZABETH, N. J.

EX-PRESIDENT OF UNION COUNTY, N. J., MEDICAL SOCIETY;  
LARYNGOLOGIST, RHINOLOGIST, AND OTOLOGIST, ELIZABETH GENERAL HOSPITAL,  
ETC.

IN 1885 it was my privilege to present for your consideration the subject of tonsillitis, at which time I pointed out what appeared to me to be the cause of certain forms of this disease—viz., uric acid. The paper was thoroughly discussed, and some of the gentlemen present expressed themselves as never having heard of the theory before. To-day, I believe, this is a generally accepted theory. I further wish to present for your consideration the effect of uric acid not only upon the mucous membrane of the throat but upon the entire respiratory tract. Especially would I call your attention to uric acid as a very important factor in the production of hay fever and asthma. In 1892, while in conversation with a medical friend, I was induced to purchase a book entitled the *Relation of Alimentation and Disease*. This book contains a chapter on asthma, its cause, pathology, and treatment. The chapter begins thus:

"All heavy horses are hogs. Heavy horses do not know when they have eaten enough. Heaves in horses corresponds to or is the same kind of disease in them that asthma is in man. All asthmatic people are unhealthy feeders and overeaters. They have a craving to keep the stomach full."

This and many other similar expressions I read to my asthmatic patients, and almost without exception they expressed themselves in very forcible language as to the idiocy of the author of that chapter. Some of them admitted, however, that their attacks came on shortly after eating, and others said they were small eaters; and

in some instances I knew this to be true. The author of that book goes on to say that "asthmatics are all dyspeptics of an especial type. They are all flatulent with carbonic-acid gas. Their stomachs are full of fermenting products. This special type of dyspepsia always develops a 'gravelly diathesis.'"

Although I do not accept the teaching of this author or agree with him in his mode of treatment, I must, however, acknowledge that my first insight as to the cause of the disease, or rather one of the important factors in the production of hay fever and asthma, came from the perusal of that book. I have constantly kept in mind the thought that the respiratory mucous membrane was in some way or other irritated by uric acid. I not infrequently see a peculiar reddened and glazed appearance of the mucous membrane of the pharynx, and often an cedematous soft palate and pillars of the fauces, with dilated and tortuous blood-vessels, which, after exhausting all other methods of treatment without success, will immediately clear up under salicylate of sodium.

The exact mode of production of uric acid in the body is still a matter of uncertainty, but, according to the majority of workers in this field, it is undoubtedly associated with nitrogenous metabolism, and the acid represents an imperfectly oxidized form of nitrogenous material. The final destination of uric acid is its conversion into urea, but from lack of perfect oxidation in the tissues this process is checked.

I determined to examine the urine, the blood, and the sputum of these patients and see if it was not due to excess of uric acid within the system. From the sputum I gained but little knowledge, because it was sometimes the secretion from the upper pharynx, sometimes from the bronchial tubes, and always more or less mixed with saliva. From the blood I gained this fact, that when the patients suffered most the blood was the most strongly alkaline (at which time it is richest in uric acid). I found the urine in some cases loaded with uric acid or urates, and in others it contained but little. I worked along this line, and it was uphill work, for many times when I supposed I had established this theory to my entire satisfaction I was met by some obstacle which almost annihilated my pet theory. Occasionally, however, I would see something which would give me fresh courage, and to-day I feel confident that uric acid is a potent factor in the production of hay fever and asthma. Of course, I allude to the asthma following hay fever. In reading Dr. Haig's book on uric acid I was led to see why so many of my cases did badly on salicylate of sodium. He does not mention asthma as being due to uric-acid diathesis, but I think I can establish that fact, and he will help me to do it by showing me errors in the administration of certain drugs. He has shown that quinine, in small doses, squeezes uric acid out of the spleen, thus producing uric acidemia, while a larger dose—six to fifteen grains of the sulphate—will

\* Read before the meeting of the District Medical Society of the County of Union, held in Plainfield, N. J., October 11, 1896.

have the action of a sulphate, which clears the blood of uric acid and thus benefits these cases. I have frequently benefited asthmatics by ten grains of quinine, and I know this to be the basis of a popular "quack cure."

He has shown that opium, cocaine, antipyrine, caffeine, strychnine, acids, iron, lead, lithia, manganese, calcium chloride, acid phosphate of sodium, some sulphates, chlorides, mercury, the nitrites, and some hyposulphites, either directly or indirectly raise the acidity of the blood or form insoluble compounds with uric acid. All these substances diminish the excretion of uric acid and bring about its retention and accumulation in the body. They drive the urates out of the circulation into the joints and fibrous tissues, also into the liver, spleen, and other organs.

Acidity of urine bears a fairly constant relation to urea, both tending to rise and fall together, and the relation given by Haig (one of acidity to 6.6 of urea) is very constant. "Whatever raises urea raises acidity, and *vice versa*. On the other hand, the alkalies (except lithia), phosphate of sodium, and compounds of salicylic acid, increase the excretion of uric acid in the urine, and for a time also increase the amount of it in the blood by raising the alkalinity of that fluid." If these statements are correct—and I have no reason to doubt them, as they agree with some observations made by myself—I should at least be able to make some impression upon my hay-fever patients, if, as I have stated, uric acid is a factor in its production. Since Bostock first described the affection, in 1819, it has been written upon largely by English and American authors, and I think it is pretty well established that three important factors are essential for the production of the disease:

1. The predisposing constitutional condition.
2. An external irritant.
3. A pathological condition of the nasal mucous membrane.

The predisposing constitutional condition is a neurosis, and who can say that this condition of the nervous system is not due to irritation by uric acid? It is a recognized fact that neurasthenia and lithæmia go hand in hand.

The second factor is an external irritant. I care not whether this be the emanation from certain plants, dust, odors, pollen, or any other mechanical irritant, my experience with mucous membranes has shown me that uric acid is a very important irritant, and I can see no reason why it should not act as such in autumnal catarrh.

The third factor is a pathological condition of the nasal mucous membrane. This may or may not be the result of irritation, and, so far as I can see, the uric-acid theory combines all three of these factors, for it not only induces a neurosis, but acts as a local irritant, which brings about pathological changes of the nasal mucous membrane. It is not necessary for me to say

anything about the symptoms of this peculiar disease, as you are all familiar with them, but I can not but allude to the paroxysmal sneezing, which is very apt to be worse about 4 A. M., or just as the patient arises in the morning. In most of the text-books it is set down that the sneezing is due to irritating dust or pollen grains. This I must deny, inasmuch as there is no dust or pollen grains in the bedchamber at that hour in the morning. In my opinion it is due to the neurotic tendency, and until I found that it occurred on dark or rainy days I ascribed it to the action of sunlight. I am now of the opinion that it is due to uric acid, since you will remember the blood at this hour is strongly alkaline, and there is more uric acid circulating in this fluid.

This brings me to the important part of this paper, Can we do anything to relieve our hay-fever patients? and before giving you my experience I want to quote Dr. Bishop, of Chicago, who has recently published a very interesting article on this very subject, and I may say truthfully that I was not aware when I wrote my previous remarks that others were working in the same field. This, however, encourages me to continue my observations, for I now feel that I am not alone in my belief.

Dr. Bishop says (in the July number of the *Laryngoscope*): "An excess of uric acid in the blood causes hay fever, or nervous catarrh. Attacks can be stopped by precipitating the excess of uric acid from the blood by rendering the latter less alkaline with an acid treatment." He, too, refers to Haig, and has evidently absorbed some of the ideas which caught me. He goes on to say: "While pursuing the study of gout and allied diseases dependent upon lithæmia, I was struck with the close analogy between the conditions present, with their local manifestations, and the various phenomena of hay fever. The theory that the paroxysms of hay fever are due to a uric-acid toxæmia is not antagonistic to the present status of medical opinion or surgical treatment; but, on the contrary, explains questions that were inexplicable before. The uric-acid hypothesis explains why some persons suffer from attacks under certain conditions in winter as well as during the warm months."

The periodicity of hay fever has a counterpart in migraine, which comes once in every seven, ten, fourteen, or thirty days, for years or for life. But enough has been said to lay the base line of a treatment that has proved vastly more successful than any other thus far devised.

I must admit that I am not so sanguine as Dr. Bishop, and yet I want to lay before you, in an impartial manner, the results of my labors in this direction. You will remember a few years ago several eminent rhinologists, chief among whom was Dr. Daly, of Pittsburgh, and Dr. Roe, of Rochester, advocated the theory that it was "a local chronic disease, upon which

the exciting cause acts with effect." They had in their minds, however, that the exciting cause came from without and not from within. I have cured some cases by removal of hypertrophies, spurs, polypi, etc., but I am satisfied they would still have their hay fever had I not made some change in their diet. This is the age when the medical profession at large is recognizing lithæmia, not only by swollen and painful joints, but by disease of the eye, the ear, the throat, the heart, the spleen, the liver, the gastro-intestinal tract, and, in fact, almost every organ in the body will show evidences of uric-acid poisoning.

Just as the dermatologist often recognizes eczema as an expression of uric acid, so do I recognize hay fever as a lithæmic condition. If you will consult the appended table you will see that ten out of the eighteen cases had eczema in some form or other. If uric acid is the important factor in the production of hay fever and asthma, why is it that it usually makes its appearance about the middle of August, especially when most people eat but little meat during the summer? In health about five to eight grains of uric acid are secreted every twenty-four hours, and it is readily soluble in the blood, which is slightly alkaline. If there is increased formation of this acid no harm results so long as it is promptly eliminated and the ratio between it and the urea is not disturbed. Anything which will produce a low nutrition will produce uric acidæmia. About the middle of August you will find a marked change in the weather, when it is usually cooler and often damp for a day or two. Invariably, as soon as this change comes you will find the hay-fever symptoms begin. I have records of the weather for the past six years, and you can almost to a certainty pick out the date of attack by the drop in temperature. This year it was about the 8th of August, and again on the 14th, when the highest temperature was 74° and the weather cloudy. The table shows that my first cases this year began on the 10th, and six of them on the 15th.

The sudden drop in temperature diminishes perspiration, raises acidity, freeing the blood from uric acid and driving it into the tissues. In two days the temperature suddenly goes up, and then you have a uric acidæmia which irritates the already exhausted nervous system and mucous membranes. Nutritive disturbances are brought about by overdrinking, especially when combined with deficient muscular exercise. Once irritated, the respiratory tract is kept in a constant state of irritation until the uric acid is driven from the blood by the onset of cold weather.

I do not mean to say that every case of uric-acid diathesis is a hay-fever subject, any more than I would say every such case had eczema, but I do mean to say that there is a very close relationship between uric acid and hay fever, and I do say that every patient having a neurasthenic tendency, if you please, and a pathological mucous membrane of the respiratory tract is irri-

tated by uric acid, and thus far my observations have led me to suspect it in every case of periodic hyperæsthetic rhinitis. In the treatment of these cases the greatest care must be exercised. You must ever keep in mind that alkalies, salicylate, etc., produce a uric acidæmia so long as there is an increase of uric acid within the system. During the attack they must be used with care and in small doses. I have certainly increased the severity of an attack by giving ten grains of salicylate of sodium three times a day. During the attack it is better to free the blood from uric acid by the administration of an acid. Aromatic sulphuric acid or phosphoric acid acts very well. After freeing the blood, gradually extract the uric acid from the tissues by two- or three-grain doses of salicylate of sodium (given three times a day), cut off the acid-producing foods, such as meat, beer, wine, cider, lemonade, etc. Keep your patient's nervous system in the best possible condition by proper feeding, hygienic measures, and nerve tonics, if necessary. See that no polypi, spurs, or hypertrophies exist in the nostrils. Begin a crusade against uric acid six weeks or even two months before the time of attack.

For the local relief, I have found menthol and camphor in liquid alboline, very gently sprayed into the nostrils, effectual in some cases. There are cases, however, which are apparently irritated by this solution, and for these I have found, if I would contract the tissue with a six- or ten-per-cent. solution of cocaine, and then gently coat the turbinate with a thin film of flexible collodion, they would experience relief. For the itching and irritation of the conjunctiva, hot water or yellow ointment rubbed into the conjunctiva will afford relief.

I can not close this paper without expressing my belief of the use of lithia. For the past three years I have failed to see a case of uric-acid diathesis benefited which I could ascribe to the action of lithia. In other words, the amount of water which these patients are obliged to take is, in my opinion, the factor for good, and not the lithia. Haig goes so far as to say that "lithia is a good solvent of uric acid in the test-tube, but in the body not only is it a poor solvent of that acid, but it actually combines with the phosphates in the blood and prevents its action on uric acid, so that the fact is lithia retards rather than increases its excretion."

I have hinted at rather than given any definite plan of treatment, and hope you will next season be able to give me the benefit of your experience. I think I can truthfully say that every patient on the list has received some benefit so far as the hay fever goes. This can not be said of their asthmatic symptoms, however, as three of them suffered quite as much as in previous years, but I have seen enough of the treatment to encourage me to begin early next season, and I feel confident I can at least mitigate their symptoms.

\* Did not carry out treatment.

## EYE STRAIN AS A CAUSE OF EPILEPSY, AND THE RESULTS OF EYE TREATMENT.

(A REPLY TO DR. FREDERICK PETERSON.)

By AMBROSE L. RANNEY, A. M., M. D.

DURING my summer vacation, the letter of Dr. Peterson in your issue of August 8, 1896, demanding that I produce a single instance of the cure of epilepsy by eye treatment, and containing the implied insinuation that I had never had such a case, has remained unanswered.

In order that the reader may appreciate the origin of this correspondence and the points at issue, before I endeavor to make my final reply, I think it wise to give the following *résumé* of the letters already published by Dr. Peterson and myself in your *Journal* relative to reflex epilepsy.

On June 20th I took issue with Dr. Peterson when he made three statements in a contribution in this *Journal* (June 6, 1896):

1. That "reflex epilepsy is so rare that the proportion of cases in which a reflex cause will be found is certainly not above one or two in a thousand."

2. That "authentic and trustworthy instances of the kind recorded in literature could easily be counted upon the fingers."

3. "That the removal of reflex irritation will seldom alter the course of the disease."

I shall to-day confine my reply to these three points only.

All side issues must be avoided, in order that the reader shall not have his mind at any time diverted from the quoted propositions of Dr. Peterson. These I believe to be incorrect and hasty.

Unfortunately for the general information of the reader, neither my engagements nor health will permit at present of an exhaustive search throughout the medical literature of the past twelve years for all cases of reflex epilepsy that have been treated by dentists; by the removal of nasal growths, scars, etc.; by the fixation of the kidney; by the removal of the ovaries and treatment of the various organs of the pelvis; by trephining of the cranial vault; by circumcision; by massage of the testicles; and by various other steps that have been employed in cases of epilepsy with reported restoration to health.

To prepare a table that would be worthy of record as an exhaustive *résumé* of the reflex causes of epilepsy to date would require (as Dr. Peterson knows) many months of research and a proportionate amount of correspondence—while it would serve no purpose to me, except to substantiate a statement made by me, viz., "that hundreds of cases of cures of epilepsy by the removal of reflex causes have been reported in medical literature."

I feel that I can (in justice to myself) employ my personal time to far better advantage in my own line of work, and that I should not be called upon by any one to report upon the work of others, or to defend their position. The request of Dr. Peterson that I do so is one of the side issues that might be productive of interesting data; but such research is not essential to the refutation of his published deductions (as quoted), because more direct facts are attainable with less labor on my part from my own published cases.

Neither does it pertain to fair argument to ask or to answer such questions as these:

"Does he (Dr. Ranney) know how many patients with incurable epilepsy are now undergoing treatment by neurologists, who had previously undergone treatment by himself and other oculists in the hope of cure?"

Would not such a question apply equally well to any method of treatment? Has any one ever maintained that epileptics could always be cured? What point can be established by any such irrelevant inquiries? Do they not strike any candid reader rather as an attempt to cast a slur upon an antagonist than an effort to deal fairly with matters in dispute?

There has been manifested in the past by some neurologists of note an apparent desire to destroy the value of carefully kept records, by lines of fine distinction in reference to epileptic patients when treated by oculists, that do not obtain when any medicinal treatment is discussed.

This statement is not an imaginary one; nor am I the first to make it in print. It takes a fair-minded as well as logical intellect to meet distasteful facts in a kindly spirit; and quibbles over the exact type of epileptic seizures that have occurred in each patient have little value clinically as a rule, and are too often but subterfuges to avoid the conclusions that most honest men would arrive at.

I think I can safely assert that it would be a difficult matter to keep a more complete and scientific record of any individual case than by the system employed by me in my office demands. The very nature of the work compels the most exact records of minute details, made at very frequent intervals, and upon printed blanks specially ruled for the purpose.

There can be no "personal equation" in the records or the published reports. The tests are mathematically correct; the instruments employed are scientifically precise, and the results of each test are recorded (in the proper column of the printed blank) when made.

In your issue of July 18, 1896, I made use of certain pertinent inquiries relating to any future analysis of my cases when I said:

"Dr. Peterson apparently to fear to meet the array of cases that will surely be brought sooner or later to his notice, when he says that he will exclude in his count of authentic and trustworthy cases all in which the existence of 'genuine epilepsy' is not well established.

"I should like Dr. Peterson to put in print just what he intends to exclude as not 'genuine' cases of epilepsy. Are all genuine cases to be those that did not get well, and is some other term applicable to those in which the patients recovered? Is this fine distinction to be hereafter exercised on all cases in Dr. Peterson's clinic and others, with proofs of the 'genuine' type of every case, or is it to be reserved as a weapon to annihilate (with one sweep) all reported cases of restoration to health by eye treatment?"

"Would it not be sad to think of a judge on the bench giving out decisions in *ex-cathedra* fashion on questions of vital moment after he had thrown out or destroyed all the evidence that failed to establish his preconceived judgment? Is it not amusing to discuss, even for an instant, the possibility of evidence being so tampered with, suppressed, or distorted?"

These demands on my part for explicit statements as to what Dr. Peterson regards as positive indications of "genuine" epilepsy were certainly but fair to myself—yet I have thus far received no enlightenment in reply.

In this controversy, this is a very serious matter. The diagnostic symptoms of epilepsy ought to have been positively and finally stated by Dr. Peterson before any cases were brought forward by me at his demand for his critical analysis and certain rejection (if such be within the bounds of possibility). Must the "epileptic cry" be present? It seldom, if ever, is observed in cases of *petit mal* (one of the most intractable types of epilepsy); yet such attacks are classed by all authors as a form of epilepsy.

Must the patient froth at the mouth to satisfy my critic? Must the tongue be bitten? Must blood show in the saliva? Must the patient have a well-defined aura? Must the patient fall (if standing, when the seizure comes)? None of these symptoms usually occur in attacks of "*petit mal*."

When my cases have been read and analyzed by Dr. Peterson I shall expect (as will all fair-minded readers of this controversy) not a wholesale rejection of cases that do not fit his theories; not a mere assertion on his part that he does not think some of the records satisfactory; not a "straining at gnats," or quibbles over trivial matters; but a fair, dispassionate, judicial statement of what facts in each individual case are wanting to justify its acceptance by him and the medical fraternity at large.

To escape the facts that he meets by offering the absolutely ridiculous explanation that in any cases where eye treatment has cured "genuine" epilepsy (if such an admission is possible) he must attribute success purely to suggestion—a sort of permanent mental hypnotism of the patients—will not answer the requirements of this controversy.

I quote from my letter of July 18th a few paragraphs relating to this point, as follows:

"This explanation is not new! It was lately hashed up and dressed in attractive garb by Dr. Casey A. Wood, of Chicago (*New York Medical Journal*, August, 1894), and my letter in reply is to be found by Dr. Peterson in a later issue!

"It is really hard for me to be serious in discussing so absurd an argument. The operation of a graduated tenotomy is absolutely painless; it is often performed by me upon children while they chat with me over their dolls or toys; it does not confine the patient to the bed or prevent any reasonable amusement or occupation more

than a few hours; it is not looked forward to by my patients with any dread (as a rule); and it is purposely made light of by me, both prior to and after the operative step, in order to decrease alarm or apprehension."

In my reply to Dr. Casey A. Wood, I made use of about these words:

"A good spanking or a dose of castor oil has ten times the mental suggestion of a graduated tenotomy; yet who ever recorded a cure of epilepsy or other grave neurosis from such a method of treatment with the hope of causing mental suggestion?"

Regarding "genuine" epilepsy, the chief of the clinic in which Dr. Peterson assists says in his work on *Familiar Forms of Nervous Disease* \* (page 269):

"In genuine epilepsy, on the other hand, the patient usually feels perfectly well between the attacks and presents no symptoms of nervous irritation."

To show that reflex epilepsy is to-day accepted as established, this author, in a previous paragraph, discusses the special symptoms that indicate the various forms of peripheral irritations which may exist as a cause of reflex epilepsy. He specially mentions, in this connection, the detection of scars; phimosis; vaginal irritation; uterine and ovarian disease; indigestion, flatulence, and constipation; irritations of the respiratory tract; eye strain; and impacted wax in the ears.

Although this author says, in closing, that "in his experience reflex neuroses of an epileptiform type are exceedingly rare," this is, as yet, purely a matter of opinion that further investigation may modify. It constitutes one of the most important questions in this controversy.

Let me here take up for Dr. Peterson's consideration the statement of Dr. Starr relative to the evidences of local irritation between seizures in cases of reflex epilepsies from the eyes. He says (page 269):

"If the irritation is from eye strain, the patient will complain of headache (frontal or occipital), aching in the nape of the neck, or discomfort about the eyes after using them for near or far objects as the case may be."

It must be admitted, I think, that my experience in examining the eyes of epileptic patients with special reference to defects which tend to create epileptic seizures is larger than that of Dr. Starr—especially as he states that only six cases in thirty-five hundred seen by him in his clinic belonged to the reflex class (in his opinion). Therefore, when I take issue with him on the two preceding conclusions (that I have quoted), I do so on grounds that are sustained (I think) by clinical records of the eye tests of a larger number of such cases than are easily accessible elsewhere.

In my published reply to Dr. Casey A. Wood, of Chicago (*New York Medical Journal*, September 29, 1894), after he had attempted in an article on reflex

epilepsy (*New York Medical Journal*, July 7 and 14, 1894) to cast a doubt upon the existence of eye strain unless previous eye symptoms had formed an important part of the clinical history, I analyzed a number of my reported cases from this standpoint alone.

I think I showed conclusively in my reply that eye strain could exist without any eye symptoms; and I am equally sure that occipital or frontal headache and pain in the nape of the neck (while frequently present) do not exist in every case, and are not positive diagnostic points.

My reply to Dr. Wood is too lengthy to admit of reproduction here; but it is accessible to Dr. Peterson and others, should they be inclined to dispute this assertion.

Regarding the probable percentage of eye strain in epilepsy, let us see what light can be thrown upon this undecided question by the experience of another, who has intelligently examined the eyes in a very large number of cases of epilepsy.

The essay of Dr. G. T. Stevens (which received the honor of a prize and special publication by the Royal Society of Belgium \*) contains the following statement:

"Of the eighty-nine cases examined in private practice thirty-four only have been treated and observed for any length of time beyond one or two visits.

"Of this number, five have withdrawn from treatment before obtaining any relief from important ocular defects, and should not be included in calculating the results of treatment.

"The remaining twenty-nine cases have been treated only by the removal of ocular defects. Of these twenty-nine cases, fourteen may be considered well; two, who are still under observation, are believed to be permanently relieved; three others, still under treatment, have received such marked relief that it is believed that an entire discontinuance of the malady may be expected. One, who had manifested some improvement, died of accident four months after his first visit. Seven have received temporary relief, while two have manifested no improvement."

It will be seen by the reader that in almost forty per cent. of these eighty-nine cases there were sufficient eye defects to justify attempts at their removal; and, in addition, the eye tests of a large percentage of the fifty-five cases that did not undertake the eye treatment were probably abnormal, although not so figured in computing the percentage.

Nearly fifty per cent. of the twenty-nine cases actually treated by the removal of eye strain by this author are reported as cured.

In looking over my own records of epileptic patients for the past ten years, I find an equally large percentage of cases, as Dr. Stevens reports, that have been seen but a few times by me; yet the percentage of the total

\* M. Allen Starr. William Wood & Co., 1890.

\* *Functional Nervous Diseases*. D. Appleton & Co., New York.

number of cases that exhibited sufficient ocular defects to justify (to my mind) a hope of amelioration of the epileptic seizures is very much larger than I had reason to suspect (nearly seventy-five per cent).

By these preliminary remarks (prior to an analysis of the twenty-six cases of epilepsy that have already been reported by me in detail as treated exclusively through the eyes) I have endeavored to establish the following deductions:

1. That eye strain is to-day recognized by most of the eminent oculists and neurologists as a possible factor in the causation of epilepsy and other nervous derangements.

2. That the percentage of epileptic cases in which the eye factor is important has not yet been determined; nor will it be until more work is done by oculists and neurologists in this field.

3. That eye strain does not entail, of necessity, upon its victims any symptoms referable to the eyes themselves, the nape of the neck, or the frontal and occipital regions, even when the eye conditions are extremely faulty, and in cases that have severe chronic nervous derangements as a direct result of eye strain.

4. That "intervals of perfect health between epileptic seizures" do not preclude eye strain as a cause. This is the rule with victims to sick headaches—almost all of whom owe their attacks to eye strain.

5. That eye treatment has ameliorated and most favorably "altered the course of the disease" in chronic epilepsy when practised by others as well as myself.

Before I pass to the special consideration of my twenty-six reported cases of epilepsy treated exclusively by me through the eyes, I desire to quote for the benefit of the reader some extracts from Dr. Peterson's last letter (*New York Medical Journal*, August 8, 1896). I do so because I think these quotations will bear repetition here as evidence of the kindly spirit and fair statement of facts that have thus far been exhibited toward myself.

Dr. Peterson says:

"Does any one believe that the doctor [myself] would fail to rush into print at once with a report of a cure if he had one recorded in his books? Why such a concealment of cures, when he has already reported so many failures?"

"The fact is that the claims of Dr. Ranney regarding the efficacy of eye treatment are not and will not be substantiated."

Let us take up these statements in order, and see what are the facts!

Of my published cases (to which Dr. Peterson refers), twenty-five are to be found in the *New York Medical Journal* (January and February, 1894) and one in the *Annals of Ophthalmology and Otology* (April, 1896).

When the first set of twenty-five cases was reported, one patient (Case IV) had been seven years without an attack; four cases (V, VI, VII, and X) had

passed over two years without any evidences of epilepsy; one (Case XV) had been free from fits for over eleven months; Case XIII had been well for nine months; Case XIV had been free from attacks for six months; Case I had been perfectly well for a year; Case II had had only one attack in sixteen months; and Case XII had been perfectly well for five months.\*

Is not this a somewhat startling array of "failures" that Dr. Peterson seems to have overlooked?

I am assured, moreover, by Dr. Hedges, of Plainfield, N. J. (in a letter published here), that one of the circular letters written by Dr. Peterson to him (as well as others) inquiring about my cases was immediately responded to by Dr. Hedges.

It is probable, therefore, that a report of a total absence of attacks in Case I for nearly four years was in Dr. Peterson's hands when he wrote that "I had reported nothing but failures, etc."; because the date of the letter of Dr. Hedges published here (July 7, 1897) is nearly one month prior to the date of Dr. Peterson's letter to your *Journal*, from which the last quotations are made. I trust that the mail miscarried in this particular instance.

Again, one important fact must not be lost sight of by the reader, viz., that marked and permanent amelioration of attacks in a chronic epileptic without drugs is a very decided step in advance of anything done by medication. The former proves a scientific discovery; the latter leaves both physician and patient in doubt as to when the drug may cease to control the attacks, and what the ultimate effects of the drug itself may be. Permanent cures of epilepsy are very remarkable cases and must, of necessity, attract attention and criticism.

The therapeutics of epilepsy has to-day a very discouraging aspect. The bromide treatment is no longer regarded by most authors as a method of cure; but it is still employed because it controls epileptic seizures for a time better than any other form of medication. Practically, chronic epilepsy is to-day regarded as an incurable malady by most men of large experience and positive convictions.

Because of the hopelessness of cure of chronic epilepsies by drugs and the importance of establishing beyond criticism the permanency of results of any new form of treatment, it may not be difficult for the reader to understand (although not apparent to Dr. Peterson) that an earnest seeker after truth is obliged to wait some years before he can himself feel sure that the beneficial effects of a treatment directed to a removal of a reflex cause are but temporary and misleading.

It therefore gives me great pleasure that I am requested by Dr. Peterson now to report upon twenty-five cases the histories of which were published by me nearly three years ago, and which he chooses to designate as "failures."

\* Later reports show that some of these cases have been absolutely cured of epilepsy.

Before I do so in detail, I deem it not only wise but absolutely imperative to make some pertinent remarks relative to what causes may lead to a recurrence of epileptic seizures after eye treatment; these should in no way reflect upon the previous results obtained, nor should they be justly construed as clinical evidences derogatory to the method of treatment itself.

1. As the refraction of the eye should always be considered an important factor in epilepsy, any neglect on the part of the patient to wear the glasses prescribed or any change in the formula is apt to lead to a recurrence of the epileptic seizures.

One of the worst epileptic seizures ever encountered once occurred in a patient (who had been free from epilepsy for over a year) within an hour from the time that a strong cylindrical glass fell from the frame and was replaced with the wrong side out.

The removal of a spherical glass for a day (ordered by me for constant wear) caused an epileptic seizure. Case XI may be one of this type, also Case III (see table published later).

Patients often break their glasses or frames and unfortunately get a wrong glass put in by some inexperienced or incompetent optician. They sometimes get the proper glass improperly inserted by some local jeweler after mending the frame, etc. Such occurrences are not infrequent, and a return of epileptic seizures is particularly apt to follow.

When patients are instructed to wear strong cylindrical glasses constantly, a simple bending of the frames may throw the glasses so much off axis as to create a far greater eye strain than an actual omission to wear them. Case V in the table I believe to be an illustration of this type of accident on some occasions, although he has at times caused an epileptic seizure by excessive overloading of his stomach with wine and indigestible food.

It is needless to multiply illustrations relative to this point. The greatest care and fidelity on the part of a patient, combined with intelligence and education, can alone prevent the possibility of an occasional epileptic seizure from imperfectly corrected refraction after the case is dismissed from the care of the oculist. Among ladies, who generally insist, from vanity, in wearing eye-glasses instead of spectacles, the bending of the nose clips and spring is always apt to distort the proper adjustment of the glasses and to cause unconsciously a new source of eye strain to the patient.

It can be easily understood by the reader that what originally induced epilepsy may tend to cause its recurrence, and that neither the oculist nor the method is responsible for accidents that he can not avoid or the patients always be aware of.

Suppose a victim of malaria should be restored to perfect health by drugs, but, after a renewed and prolonged exposure to malarial germs, some evidences should appear of a return of the old malady, would it in any way reflect upon the results obtained by drugs?

2. Many chronic epileptics unquestionably (in my opinion) are influenced (even after long intervals of relief from seizures) by their former "epileptic habit."

By this I mean that under conditions of extreme nervous weakness or disturbance, such as often follow severe indigestion, anxiety, fright, loss of sleep, excessive exertion, etc., these patients are peculiarly apt to have a convulsion, where ordinary patients would have simply a headache or some milder evidence of physical depression.

Such attacks, as a rule, mean nothing. They are not to be construed as precursors of a return of the old epileptic condition. They pass without causing much if any constitutional depression; and the patient goes on (as before) free from subsequent seizures until some similar exciting cause occurs to induce one (Cases II, XXI, and XXVI, I think illustrate this point).

3. During the treatment of heterophoria\* (which in epileptics is almost universally "latent") the oculist never knows positively until a year or two has elapsed whether he has established an absolute and permanent "orthophoria."† So long as any latent muscular trouble remains, occasional epileptic seizures are to be expected, even with the greatest care on the part of the oculist as to the perfect correction of the refraction of the patient and the greatest fidelity on the part of the patient as to following the directions of the oculist.

In a happy way, some one may, before the millennium, discover a drug or other process that will enable the oculist to determine at one sitting all latent heterophoria that exists in any case, as we now are enabled to measure, while a patient is under the effects of atropine, all latent error of refraction at one sitting; but, until that time, we will have to allow the patient to disclose it by piecemeal (as it were), and to patiently wait until, by proper scientific aids, we can feel sure that we are interpreting the eye tests of the patient intelligently, and relieving the burdens as fast as they are disclosed by the patients.

Prior to the discovery of atropine, this was the way that "latent" hypermetropia‡ was treated. Glasses were given to the patient as strong as he would tolerate at first; and, gradually, their strength was increased by the oculist, as fast as the patient would tolerate the increase, until the full correction of the latent hypermetropia was apparently reached.

4. It is important in all cases of chronic epilepsy, while eye treatment is going on, to be sure, if possible, that no other reflex cause exists to keep up the epileptic seizures.

While it is my custom to have the teeth, ears, and nose of almost all patients examined by experts, and the pelvic organs of many female patients carefully looked

\* A term that covers all anomalies of the ocular muscles.

† A term that means the establishment of perfect adjustment of the ocular muscles.

‡ The condition known as far-sightedness.

into by a gynecologist, with the view of eliminating all reflex factors that may coexist with eye strain, it is not always possible to state that the removal of eye strain alone in unsuccessful cases has completed the treatment, nor is it fair to infer that the eye work has been unproductive of any benefit.

A general proposition regarding the treatment of epilepsy may be thus stated: Every reflex cause that can be detected in an epileptic ought to be removed. The amelioration of the epilepsy may not come at once, and it will not come at all in a small proportion of cases; but an effort should be made in each case to give Nature every possible chance to reassert herself by relieving the nerve centres of all sources of reflex irritation.

In concluding this article, I propose now to present, what Dr. Peterson seems particularly desirous to obtain, as full a report as I can give of each of the twenty-six cases that I have published up to this date.

At considerable trouble, I have endeavored to get (by correspondence and interviews) all the latest information possible from the patients and the physicians who sent them to me—much of which I shall publish here.

CASE I.—This patient has himself reported frequently to Dr. E. W. Hedges, of Plainfield, N. J.

Concerning him, Dr. Hedges writes me as follows:

July 7, 1896.

DEAR DR. RANNEY: Replying to your letter of July 6th, in which you make inquiry as to the present condition of Mr. B. and Mrs. G.,\* both of whose eyes you operated on for the cure of epilepsy, I can only report fully in regard to one.

Mr. B. has been perfectly well ever since. He works every day and has not had a single convulsion nor anything like one since you discharged him.

Mrs. G. moved to Buffalo about two years ago, since which time I have heard nothing as to her condition. Just previous to leaving she called upon me and declared that she was a different woman, mentally and physically, since the operation; that it seemed to her as though she had been living in a dream for years past. She had gained about thirty pounds in weight, as I remember it, and certainly looked younger and better than I had ever seen her. At that time there had been no return whatever of the epilepsy.

Dr. Peterson has written to me in regard to "the patient," whom I referred to you. I suppose he meant Mr. B., and I have answered him in substance as I have written to you.

I watched these two cases for years and saw them grow steadily worse under various forms of treatment, both dietetic and medicinal, and I am convinced beyond doubt that at least some cases of epilepsy can be cured by proper operations done upon the eyes.

I am, yours truly, ELLIS W. HEDGES.

The clinical history of this case (like those of many others in the table) when originally published by me was very incomplete. It fails to give many essential facts about the seizures of this patient that can be

now supplied. The original reports of these cases were abbreviated as much as possible by me, in order to lessen the space in the *New York Medical Journal*, that I feared was being overcrowded by me at that time.

This patient had a number of attacks in my office; so that both my assistant (Dr. W. R. Broughton) and myself had ample opportunity to observe and record the clinical features of several of these seizures.

Once, while walking from my reception room to my consultation room, he suddenly stopped; his face became slightly livid, with a fixed stare; his head was twisted to one side; his fingers and arms worked convulsively; saliva drooled from his mouth; he muttered incoherently as the attack was passing off; and he urinated in his trousers. He was perfectly unconscious for a period of about ten seconds. While some of his attacks were somewhat lighter than this, he almost always urinated in his clothing.

This case is one of my reported failures, according to Dr. Peterson, although the patient has passed nearly four years without an attack of any kind.

My critic may say that this case is one of *petit mal*—which is true! But is not *petit mal* regarded by most standard authors on nervous diseases as not only a type of "genuine" epilepsy, but also as one of the most intractable types of epilepsy?

Dr. M. Allen Starr (whose assistant Dr. Peterson is) says, on page 273 of his work: "The treatment of *petit mal* is less satisfactory than that of *grand mal*. The only remedy of any service is nitroglycerin."

I quote this author because it is hoped that the published opinion of the head of the clinic may have greater weight with the assistant than that of any other author.

In spite, therefore, of the unmistakable character of these attacks and the failure to employ nitroglycerin as a curative agent, this patient made a quick and permanent recovery after the correction by me of his eye strain.

The evidence is overwhelming! The letter of the patient has been given (1894); the written testimony of the doctor and my own published records are given here; and Dr. Peterson holds (presumably) a letter from Dr. Hedges to the same effect, if he has not destroyed it.

Prior to my treatment, the records show that from two to ten attacks occurred daily. This patient had so slight a refractive error (see table) that no glasses were prescribed.

CASE II.—This patient was referred to me by Dr. J. B. Bissell, of New York, after he had consulted many physicians, among whom were Professor E. G. Janeway, of New York, Dr. St. John, of Hartford, and (also) Dr. Frederick Peterson, of New York, who ought to remember the letter he personally wrote the patient after he began with me the eye treatment.

An unfavorable prognosis regarding marked amelioration or cure had been given this patient by Professor E. G. Janeway early in 1892, who referred him to an oculist and advised the continuance of bromides. He

\* See report on Case XII and letter.

was then having typical attacks of *grand mal* on an average of one every eight weeks, in spite of the bromides.

A letter received from the patient (October 17, 1896), in answer to one of inquiry from me, states that eight attacks have occurred in five years. This is about one quarter of his average when under bromides. He also says, "My health since March 7, 1896, has never been better, and, in fact, couldn't be better."

I regard this case as one of practical cure, although occasional epileptic seizures have occurred. The patient is no longer afflicted with the severe dyspeptic troubles that persisted until I treated him, and his physical and mental condition to-day makes a marked contrast with that which existed when he was a victim to bromides.

Unfortunately, the results in this case, that might otherwise have been expected, have been delayed by his occupation. He has to work, of late, long hours as a bookkeeper, and to wear over one eye a hypermetropic cylinder and over the other eye a combination of a myopic glass and a myopic cylinder. He has also been obliged to use his eyes almost immediately after each operative step, and systematic out-of-door exercise is often rendered impossible by his business. He has once passed eight months without a seizure; again, nine months; and again, eleven months.

I feel personally convinced that he would remain entirely free from attacks if he lived out of doors and had an occupation in which he did not have to use his eyes. He is a strong, hearty eater, and needs systematic exercise to keep him in good physical shape.

(To be continued.)

## Therapeutical Notes.

**The Treatment of Piles and Pruritus Ani with Collodion.**—Dr. D. W. Samways (*British Medical Journal*, November 21, 1896) says he has found that the itching in cases of pruritus ani disappears at once on the application of simple collodion. After a few moments of somewhat intense smarting (which can be prevented by cocaine if necessary) no further itching is felt ordinarily for twelve or twenty-four hours if at all. He supposes the ether or alcohol in which the gun cotton is dissolved stops the irritation, and the collodion film, by protecting from the air, prevents its reappearance. In cases of external piles he has observed that the application stimulates the pile to contract, that the hardening film of collodion supports the pile thus contracted, and that the contracting collodion (not collodium flexile) further reduces it. It is the principle of the elastic stocking applied to the hemorrhoidal instead of the saphenous veins, he says, and with a like result. The collodion is best applied by dropping it on a few fibres of cotton wool, which are spread over the pile each morning after defecation.

**The Copper-Arsenite Treatment of Infantile Diarrhea,** as recommended by Dr. John Aulde, of Philadelphia, has been tried extensively by Dr. Hanns Krüger, of Osnabrück (*Allgemeine medicinische Central-Zeitung*, 1896, No. 58; *Wiener klinische Rundschau*, November 22, 1896), and he finds it eminently efficient. He thinks its mode of action is by destroying bacteria.

## THE NEW YORK MEDICAL JOURNAL, A Weekly Review of Medicine.

Published by  
D. APPLETON & Co.

Edited by  
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, DECEMBER 26, 1896.

### RESTRICTING THE DISSEMINATION OF MEDICAL KNOWLEDGE.

DR. GEORGE M. GOULD, of Philadelphia, has issued a circular addressed to the members of the medical profession in which he asks for an expression of opinion as to the relations between publishers of medical journals and the profession. The occasion of the request is stated to be the fact that a firm of publishers has refused to allow the editors of the *American Year-Book of Medicine and Surgery* to use in preparing their abstracts articles and illustrations that have first been printed in either one of two journals issued by the publishers mentioned. Dr. Gould thinks this action on the part of those publishers is wrong. He gives his reasons for this opinion, the chief of which is that such a course interferes with the dissemination of medical knowledge. Physicians write and publish articles, he says, in order that every member of the profession may, if possible, learn of their work, and in order that science and progress may thus be furthered and humanity benefited. To check such a dissemination of our literature in reputable publications is, he thinks, discourteous and unjust to the profession and an injury to medical science.

Dr. Gould declares that no publishers in the world, except the firm he mentions, have in the least objected to the *Year-Book's* reproduction of illustrations or making quotations or abstracts from their journals. He does not state what reason the firm in question has given for denying him and his associates the permission they sought for, or, indeed, say whether or not any reason has been given. We should imagine there must be one applying to the special case, for we can not conceive of any good to be attained or any evil to be avoided by pursuing such a course as a general rule. The firm mentioned by Dr. Gould is well known for its business sagacity, and it seems inexplicable that it should take measures to deprive itself of one of the best means of advertising its journals.

We have never been able to see what harm a journal could sustain by having its contents reproduced in abstract in other periodicals or in books, provided due credit was given, as would undoubtedly be the case with the *Year-Book*. Indeed, always with the same proviso,

we like to see entire articles reprinted from our columns. We feel that it is a good thing for the *Journal*, for it not only calls readers' attention to it, but goes to show that the *Journal* would not be thus drawn upon if it did not contain matter thought to be worth reproducing, and the more a journal is quoted the more such matter it may be held to contain, and the likelier is a person who is not at the time a subscriber to it to become one.

## MINOR PARAGRAPHS.

### BOOKS AS VEHICLES OF INFECTION.

CAZAL and Catrin (*Annales de l'Institut Pasteur*, ix, 12; *Centralblatt für innere Medizin*, December 12, 1896) have investigated from the bacteriological standpoint the question of how far books are capable of conveying disease. A book from a hospital circulating library was found to contain a number of saprophytes and in addition a few pathogenic germs, staphylococci and the *Bacillus subtilis*. Even a new book, fresh from the publisher, was not sterile, but showed only harmless bacteria. The authors infected several books with known pathogenic species, and a few days later implanted bits of the leaves in culture media. The streptococcus, the pneumococcus, and the diphtheria bacillus were thus found to be communicable by books, but the typhoid organism and the tubercle bacillus gave negative results.

### A NEW ANIMALCULE FOUND IN ASCITIC FLUID.

DR. E. VON LEYDEN and Dr. F. Schandinn (*Sitzungsbericht der königlicher preussische Akademie der Wissenschaften zu Berlin*, July 30, 1896; *Centralblatt für innere Medizin*, November 14, 1896) have discovered in ascitic fluid from the living human subject an amoeba-like rhizopod to which Schandinn has given the name *Leydenia gemmipara*. It was found in two patients, one of whom was a young woman with aortic insufficiency, and the other a man with cancer of the stomach.

### THE BUBONIC PLAGUE IN LONDON.

THERE has recently been something of a panic in London on account of the arrival of a ship in port with the Chinese plague on board. It was of short duration, however, for the sanitary officials, acting according to the enlightened methods that now prevail, did all that was called for and public alarm was at once at an end.

### ITEMS.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending December 22, 1896:

DISEASES.	Week ending Dec. 15.		Week ending Dec. 22.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	23	9	20	2
Scarlet fever.....	145	10	140	3
Cerebrospinal meningitis....	0	0	2	2
Menses.....	123	6	166	8
Diphtheria.....	295	35	262	36
Tuberculosis.....	89	83	139	109

**The American Physiological Society.**—The ninth annual meeting will be held in Boston, on December 29th and 30th. The provisional programme includes the following titles:

Studies in the Physiology of the Mammalian Heart, by Dr. W. T. Porter; On the Duration of Cardiac Standstill with Different Strengths of Vagus Stimulation, by Dr. T. Hough; Some Experiments on the Relation of the Inhibitory to the Accelerator Nerves of the Heart, by Dr. R. Hunt; The Exhibition of Plethysmographic Curves obtained during Sleep, with Remarks, by Dr. W. H. Howell; The Relation between Height, Weight, and Age in Growing Children, by Dr. H. P. Bowditch; An Experiment on Telegony, by Dr. C. S. Minot; On the Contraction of the Stomach produced by Direct Stimulation and by Stimulation of the Vagi with the Faradaic Current, by Dr. S. J. Meltzer; An Experimental Investigation of Some of the Conditions influencing the Secretion and Composition of Bile, by Dr. F. Pfaff; The Production of Sugar from Gelatin in Metabolism, by Dr. G. Lusk; Demonstration of a Method for the Isolation of the Mammalian Heart, by Dr. W. T. Porter; Demonstration of the Reaction of the Stomach to Faradaic Stimulation, by Dr. S. J. Meltzer; Demonstration of a Convenient Form of Apparatus to Avoid Explosions in Gas Analysis, by Dr. G. T. Kemp; The Structure of the Sympathetic Ganglia of Vertebrates with Demonstration of Preparations, Remarks on the Ending of Nerves in Muscle Tissue, with Demonstrations, by Dr. G. C. Huber; The Functional Development of the Cerebral Cortex in Different Groups of Animals, by Dr. W. Mills; The Restoration of Co-ordinate Power after Nerve Crossing, by Dr. R. H. Cunningham; The Proteolytic Action of Papan, by Professor R. H. Chittenden; Experiments on the Physiological Influence of Alcohol, by Dr. C. F. Hodge; The Physiological Action of Nitrous Oxide, by Dr. G. T. Kemp; On the Bactericidal Effects of Lymph from the Thoracic Duct, by Dr. S. J. Meltzer. Demonstrations of apparatus will be given as follows: A spring cylinder chronograph for spark records; a lever system to illustrate the action of muscles in relation to joints; a form of student's myograph; a modification of the location reaction apparatus, by Dr. G. W. Fitz; and preparations of the nerve cell under acute alcoholic poisoning, by Dr. C. F. Hodge.

**The Late Dr. Déclat.**—A respected contributor sends us the following for publication:

"The death, recently announced, of Dr. Déclat at his villa at Nice, France, is a great loss to science, as to him justly belongs the honor of having created the antiseptic methods of treatment now universally employed. In 1861, at the Hôpital St.-Jean de Dieu, Paris, he made the first phenated applications and dressings, and in 1863 the first phenated hypodermic injections, publishing his treatise on the use of phenic acid in 1865, that has passed through four editions. It was not till 1868 that Lister employed phenated dressings and spray in surgery. In the words of the *Paris Figaro*: 'It is to Dr. Déclat that the world owes the antiseptic method in medicine and surgery. The number of lives saved thereby is incalculable, but some idea of its greatness may be formed from the statement that in the maternity hospitals of France the mortality from puerperal fever has fallen since the introduction of the antiseptic system from twenty-five to thirty in the hundred to five or six in the thousand. Dr. Déclat was a skillful practitioner, an accomplished gentleman, and a true friend. The honor withheld during his lifetime, on account of enmities unfortunately excited, will now doubtless be paid to Déclat dead.' It will be recollected that he visited this country in 1881 on the occasion of the presentation by the French nation of the Bartholdi Statue of Liberty. He crossed the continent, and was well received at various medical centres from New York to San Francisco."

**The Albany Medical College Alumni Association of Greater New York.**—At the annual meeting, held on December 17th, the following-named gentlemen were elected officers for the ensuing year: Dr. William H. Thomson, president; Dr. Reuben B. Burton, vice-president; Dr. Warren C. Spalding, secretary; Dr. Henry S. Brooks, assistant secretary; Dr. Edward F. Quinlan, treasurer; and Dr. William Stevens (for two years), Dr. Frederic Loughran

(for two years), Dr. H. C. F. Muller, of Brooklyn (for one year), and Dr. L. N. Lauchars, of Hempstead (for one year), governors. The annual banquet will be held on Thursday, January 21st.

**The New York Celtic Medical Society.**—At the last regular meeting, on Wednesday, December 23d, the order for the evening was as follows: A paper entitled *Diatheasis and its Influence on the Respiratory Canal*, by Dr. D. T. McDonald; scientific communications; exhibition of instruments and specimens; and presentation of cases.

**The Buffalo Academy of Medicine.**—At the last regular meeting, on Tuesday, December 22d, the order for the evening included the following papers: *The Ætiology and Pathology of Uterine Displacements*, by Dr. M. A. Crockett; and *The Diagnosis and Treatment of Uterine Displacements*, by Dr. Stephen Y. Howell.

**The Brooklyn Medical Society.**—At the last regular meeting, on Friday, December 18th, the order for the evening was as follows: *Some Remarks on Genu Valgum and its Treatment*, by Dr. Edwin A. Hatch; *Eye Strain*, by Dr. James W. Ingalls; and a demonstration of the bacillus of the Chinese plague, by Dr. Ezra H. Wilson.

**The Richmond Academy of Medicine and Surgery.**—At the last regular meeting, on Tuesday evening, the 22d inst., a discussion on Stone in the Kidney was to be opened by Dr. Charles R. Robins.

**The French Hospital.**—Dr. W. Whitehead Gilfillan has been appointed ophthalmologist to the hospital.

**Change of Address.**—Dr. Carroll E. Edson, from Boston to the McPhee Building, corner of Seventeenth and Glenarm Streets, Denver.

**Naval Intelligence.**—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending December 19, 1896:*

BALDWIN, L. B., Surgeon. Detached from the U. S. Steamer Newark and ordered to the U. S. Steamer Puritan.

EVANS, S. G., Passed Assistant Surgeon. Detached from the U. S. Steamer Pinta, on reporting of his relief, and ordered to the Naval Hospital, New York.

ROTHGANGER, G., Passed Assistant Surgeon. Detached from the U. S. Steamer Patterson and ordered to the U. S. Steamer Pinta.

#### Society Meetings for the Coming Week:

MONDAY, December 28th: Medical Society of the County of New York; Boston Society for Medical Improvement; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Maine Academy of Medicine and Science (Portland); Baltimore Medical Association.

TUESDAY, December 29th: Boston Society of Medical Sciences (private).

WEDNESDAY, December 30th: Auburn, N. Y., City Medical Association; Berkshire, Massachusetts, District Medical Society (Pittsfield).

FRIDAY, January 1st: Practitioners' Society of New York (private); Baltimore Clinical Society.

SATURDAY, January 2d: Clinical Society of the New York Post-graduate Medical School and Hospital; Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

CARLEY—KING.—In Brooklyn, on Tuesday, December 15th, Dr. William R. A. Carley and Miss Emily Amanda King.

HAWXHURST—BENTON.—In Brooklyn, on Thursday, December 17th, Dr. Henry Dawson Hawxhurst and Miss May Ethel Benton, daughter of Dr. Stuart H. Benton.

HOLSTON—CONKLIN.—In Mount Morris, N. Y., on Wednesday, December 16th, Dr. J. D. Holston, of Amos, West Virginia, and Miss Harriet E. Conklin.

KING—BARRINGER.—In Florence, South Carolina, on Tuesday, December 22d, Dr. Claude Evans King, of Mayesville, South Carolina, and Miss Mary Augusta Barringer.

RATCLIFF—CHANDLER.—In Mico, Mississippi, on Monday, December 14th, Dr. H. F. Ratcliff and Miss Docie Chandler.

#### Died.

JONES.—In Leavenworth, Kansas, on Wednesday, December 16th, Dr. Selden W. Jones.

SEARS.—In Birmingham, Alabama, on Sunday, December 13th, Dr. J. W. Sears, aged sixty-seven years.

### Proceedings of Societies.

#### SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION.

*Ninth Annual Meeting, held in Nashville, on Tuesday, Wednesday, and Thursday, November 10, 11, and 12, 1896.*

The President, Dr. E. S. LEWIS, of New Orleans, in the Chair.

**Vaginal versus Abdominal Section for Pus in the Pelvis.**—Dr. W. D. HAGGARD, Jr., of Nashville, recounted the transitional periods in the treatment of pus in the pelvis—vaginal puncture superseded by abdominal section and removal of pyosalpinx, and removal of the uterus and its annexa *per vaginam* by the French and through the abdomen by the American school. These operations had given way to modern vaginal section and evacuation and drainage of all pus pockets. The abdominal route afforded visual inspection of the field. The attack on morbid masses could be made with safety to visceral integrity. If pus accumulations were multiple, rupture and peritoneal soiling were inevitable; that was the supreme disadvantage of abdominal incision. The author had often seen the pelvis deluged with pus with impunity. He had also seen patients die within twelve hours from fulminant sepsis from peritoneal contamination. He referred to a mortality of 18.5 per cent. in a series of collected cases of laparotomy for pus, done in five metropolitan hospitals in the last year, and asked what it must be in the "unheard-from precincts." The abdominal method offered the best approach in tuberculous inflammation of the ovaries and tubes and in cases of small unilateral pyosalpinx. The author referred to the advantages of exploring the pelvis for retro-uterine tumors and the annexa by vaginal section.

The situation of pus in the pelvis in most cases made vaginal incision extraperitoneal, a minor procedure giving major results. There was no shock, there was no risk, there was no disturbance in convalescence. In prolonged sepsis from large abscesses, posterior section and drainage were life-saving procedures. The special indications were: 1. Early cases of acute suppurating salpingitis. 2. Incipient post-puerperal peritonitis. 3. Large pyosalpinx and true pelvic abscess. The first group included early gonorrhœal and abortion cases. In puerperal cases, incipient peritonitis and puddles of pus in Douglas's

### Births, Marriages, and Deaths.

#### Married.

BAILEY—WOODEN.—In Brooklyn, on Thursday, December 17th, Dr. Frederick Randolph Bailey, of Elizabeth, N. J., and Miss Minnie Josephine Wooden.

space imperatively demanded incision. Should simple pus-letting in any of these cases not effect a cure, a subsequent operation for the removal of relics of previous ravages could be done without the dangers incurred in the presence of pus. The field of vaginal section was to prevent suppuration in early cases, to anticipate it in puerperal cases, and to save life in desperate cases. Its application to the pelvic inflammatory processes and to pus in the pelvis was one of the greatest surgical triumphs of the age.

Dr. JOSEPH TABER JOHNSON, of Washington, said that, while the vaginal method had a great many points in its favor and was being resorted to more and more in cases of large pus collections in the pelvis, yet those who had been familiar for a considerable time with the abdominal route could operate more conveniently and dexterously by this method and with greater safety to the patient than by the vaginal. He could not agree with the speaker that the vaginal operation might be done without any risk to the patient. Sometimes in operating through the vagina for the purpose of removing the uterus and its annexa, or for large pus collections high in the pelvis, where it was necessary to manipulate the parts a good deal and to do a thorough enucleation, the surgeon was likely to tear the intestine, the bladder, the ureter, or a large vessel which was out of sight. In such cases the abdominal was much safer than the vaginal route.

Dr. CHARLES P. NOBLE, of Philadelphia, did not feel that either the abdominal or the vaginal method possessed all the advantages, but if restricted to one or the other he should prefer the abdominal rather than the vaginal route. An objection formerly urged against the abdominal route was the large percentage of hernias which followed this method. Only a week since he had tabulated the operations he had done for four years, which amounted to 397 abdominal cases, in which he had used the buried suture in closing the abdominal wound. Of this number the wounds had suppurated in seven cases, while in 390 they had healed by primary union. Among the seven patients in whom suppuration had occurred, one had had a hernia. There had been a large umbilical hernia in one of the 390 cases. Aside from these two cases, he had not had any hernias in his operative work for the last four years where the buried suture had been used. If the patient was in a condition to permit the surgeon to do ideal work, he thought the question of hernia was such an insignificant one that it might be left out of consideration.

Dr. HOWARD A. KELLY, of Baltimore, said that, whenever possible, pus in the pelvis should be treated by vaginal puncture or section posterior to the cervix, without sacrificing any of the uterine appendages. A large percentage of the patients thus treated would have no further discomforts. Illustrative cases were cited. One of the principal arguments advanced by advocates of the vaginal route in removing the uterus, the tubes, and the ovaries was the excellent drainage that could be secured by this method. In Dr. Kelly's opinion it was unnecessary to take out the uterus to get drainage.

Dr. L. S. McMURTRY, of Louisville, said that a deep impression had been made upon the profession in the last two years by the vaginal method of operating for pus in the pelvis. This procedure, however, was by no means a new one. Battley, in his original operations upon the ovaries, had attacked the pelvic organs through the vault of the vagina. The method of attacking accumulations of pus in the pelvis by vaginal puncture

and drainage had been the universal practice of abdominal surgeons for a long time. The sacrifice of the uterus in the majority of cases of suppurative pelvic inflammation was unnecessary. Surgery should be confined within the limits of removing only such diseased tissue or organs as it was necessary to remove for the complete cure and restoration of the patient.

Dr. J. WESLEY BOVEE, of Washington, objected to anterior colpotomy in dealing with pus cases unless the accumulation of pus was on top and in front of the bladder. He thought that in these cases drainage through the anterior vaginal route could not be done, and the pus could not be reached in many cases. He believed it was not necessary to remove the uterus at the same time the tubes were taken out. He did not want to be understood as being opposed to the vaginal route in very urgent cases.

Dr. R. B. MAURY, of Memphis, had during the last two years thoroughly studied the subject of vaginal hysterectomy, as he had done quite a number of these operations without any mortality, any accident, or unpleasant result. But he would not undertake to say that we ought to substitute it for laparotomy. Both abdominal and vaginal hysterectomy were operative measures that surgeons must avail themselves of according to the circumstances of the case. Dr. Maury cited the histories of two patients that he had treated within the last thirty days, which beautifully illustrated the advantages of the two methods.

Dr. W. E. B. DAVIS, of Birmingham, Alabama, said the practice of incising pelvic abscesses was so old that it hardly required discussion, but the method of attacking pyosalpinx by vaginal section was comparatively recent. Unquestionably vaginal incision for pus confined to the tubes and ovaries would save these important organs in a good proportion of cases. In all cases of large pus collections in the pelvis nothing should be done more than to incise the abscess and drain, and then later on the surgeon should be prepared to do an abdominal section, if necessary, but he thought the surgeon would rarely have occasion to do this. Total ablation of the uterus and its annexa was unnecessary in many of the instances in which it was practised by some surgeons.

**Cholelithiasis.**—A paper on this subject was contributed by Dr. A. M. CARTLEDGE, of Louisville, in which the author reported several interesting cases. He dwelt upon cholecystostomy and cholecystenterostomy, pointing out the indications for each operation. He considered cholecystostomy the only operation that was applicable in the cases cited. In his opinion there were no cases that primarily demanded cholecystenterostomy.

Dr. JAMES McFADDEN GASTON, of Atlanta, agreed with the speaker that, in ordinary cases of gallstones in the gall bladder, with obstruction of the cystic duct, the simplest procedure was to lay open the abdominal wall, attach the gall bladder to the incision, and remove the gallstones. But in a large proportion of cases of complete obstruction he doubted whether there would be restoration of the flow of bile through the cystic duct into the gall bladder. With reference to the comparative value of cholecystostomy and cholecystenterostomy, the two operations were applicable to entirely different conditions. No one would operate and expect benefit from a cholecystostomy except to establish drainage for the bile in a case of permanent occlusion of the common duct, and this was the only condition in which the advocates of cholecystenterostomy had ever alleged anything for it.

Dr. JOHN D. S. DAVIS, of Birmingham, Alabama, emphasized the point that patients frequently had gallstones without the manifestation of symptoms, particularly the symptom jaundice. He did not believe that it was ever wise to resort to cholecystenterostomy as a primary procedure. The surgeon should first resort to drainage, and then, if relaxation did not take place and the flow of bile was not effected, cholecystenterostomy should be done.

Dr. GEORGE BEN JOHNSTON, of Richmond, Virginia, spoke of the diagnosis of gallstones. He was convinced that if examinations of suspected cases of gallstones were as careful and minute as they should be, surgeons would frequently find them. It had been his experience that enlargement of the gall bladder did not always occur where a gallstone existed, but that a condition which simulated enlargement of the gall bladder frequently did exist, this condition being due to the presence of numerous dense adhesions found in the neighborhood of the gall bladder, gluing it to every tissue with which it came in contact. One thing which struck him as very singular in connection with the presence of gallstones was that the size of the stone or stones seemed to make no difference in the production of symptoms. In regard to hæmorrhage, it was generally admitted that cases in which cholæmia was profound were the ones in which we were to expect hæmorrhage, and by no known method could this hæmorrhage be successfully controlled. The cholæmic condition seemed to invite a fatal hæmorrhage. The experience of operators in this field of surgery was that when cholæmia was profound hæmorrhage of a fatal character was to be expected. He considered cholecystostomy a proper procedure in all cases, except those where the obstruction was in the common duct and could not be relieved.

Dr. W. E. B. DAVIS said that surgery of the gall bladder for the removal of gallstones had given brilliant results, but there were still questions in regard to operative procedures on the ducts that were not as yet definitely settled. He did not believe the speaker referred to cholecystostomy as being the operation of choice in cases where the obstruction of the duct could not be removed, but he must have had in mind the procedure advocated by Murphy, of resorting to this operation in a case of gallstone in the gall bladder where there was no obstruction in the duct. Murphy had resorted to cholecystenterostomy instead of cholecystotomy, and he thought that Dr. Johnston did not intend to convey the idea that he would not do cholecystenterostomy where the obstruction in the duct could not be removed. Cholæmic cases were had to operate in. Perhaps in not more than five or six per cent. of the cases was the obstruction found in the common duct. Some years ago the speaker had made experiments which conclusively showed that the surgeon could incise the duct and drain with gauze without peritonitis following. A paper on this subject had been read by him before the American Medical Association in 1892, since which time he had done further experimental work in which sutures had not been used after the stone had been removed from the duct, and, while several of the patients had very nearly died from profound cholæmia, and eventually did die, yet in the cases in which this method had been resorted to the abdominal cavity had been walled off and peritonitis had not resulted.

Dr. GEORGE A. BAXTER, of Chattanooga, directed attention to the frequency of gallstones unattended with the ordinary symptom of colic, and cited an illustrative

case in which there had been found post mortem three large stones in the gall bladder.

Dr. F. W. McCRAE, of Atlanta, reported a case in which there had been repeated attacks of colic with profound cholæmia. An operation had been undertaken with the idea that the obstruction had been in the common duct, and that there had been stones in the gall bladder. When the abdomen had been opened in the presence of several physicians the liver had been found to be much enlarged and reaching almost to the umbilicus. Instead of finding the gall bladder enlarged, he had found a fibrous cord not larger than his index finger. The common duct, from disuse, had been reduced to a mere cord. A calculus had been found in the hepatic duct which extended up into the transverse fissure of the liver. He had not known what to do in this case, and, after consultation with his colleagues, he had closed the abdomen. The patient had died five days later from exhaustion. If anything could be done for such patients he would like to know it.

#### Mental Complications following Surgical Operations.

—Dr. JOHN T. WILSON, of Sherman, Texas, said that the subject of mental disorders produced by or following surgical operations had not been discussed to any great extent, and until within the past two years only a passing notice had been given to it. It was a strange fact that, while surgical operations would sometimes cause serious mental disturbance, on the other hand those same operations would sometimes cure it; especially was this the case with some melancholics. Many women who labored under attacks of melancholia caused by some disease of the genital apparatus had been cured when relieved of the physical defect by operation; others had been much improved, and yet some had received no benefit. The question might very properly be asked, why a surgical operation should produce an attack of insanity. This could no more be answered in every case satisfactorily than the question of why some persons became insane from the many other causes to which it was attributed, for in most cases the mental complications were a surprise and no good reason could be given why they should follow. In others, however, a logical explanation might be had. If the patient was a high-strung, nervous individual, easily excited, and unable to bear pain, the great and increasing dread of the anæsthetic, the operation, or both would so affect him that he would lose control of the will power and the explosion would come after the operation and reaction from the anæsthetic. In many of these cases, probably a majority, there was an hereditary taint or a strong neurotic tendency.

The author quoted Mairé, who thought that it was in those individuals who were predisposed by heredity or other grave causes—alcoholism, infectious diseases, etc.—that surgical operations gave rise to insanity. In the constituent elements of an operation which might act on the brain the two most important ones were the anæsthetic and the degree of surgical traumatism with its after-effects, of which disturbed nutrition played a very important part. When the predisposition also was considerable the anæsthetic alone might produce insanity, or it might result even after minor operations. It was, of course, necessary to take into consideration the mental state of the patient prior to the operation, especially in those graver cases where questions of life or death were frequently involved.

Dr. E. S. LEWIS, of New Orleans, related the case of a woman, forty years of age, who had been very hysterical,

upon whom he had operated for laceration of the perineum. She had manifested no evidences of insanity prior to operative interference, but during her convalescence the hysterical manifestations had increased and had been associated with delusions. Her condition had become so serious that on different occasions she had threatened to commit suicide. She had been transferred to an insane asylum, and after a thorough examination by the physician in charge an unfavorable prognosis had been given. Investigation of the family history had shown traces of insanity.

In another case, that of a woman sixty years of age, he had removed a very large adherent ovarian tumor, and the operation had been attended with considerable shock. For a few days subsequently the patient had done well, but then she had become perfectly insane. These were the only two cases he vividly remembered, although he had seen cases of temporary insanity after operations, which had passed off in the course of a few months.

Dr. W. E. PARKER, of New Orleans, had seen two or three cases of insanity in men following surgical operations, but had never been able to trace any history of the disease in the family. The insanity had occurred in alcoholics. Two of the men had been addicted to either cocaine or morphine. In the management of such cases the use of the particular drug to which the patient was addicted should still be continued in very small doses, and cut off gradually, for the reason that great prostration often followed the sudden interdiction of a habit that had been continued for many years.

Dr. R. B. RHETT, of Charleston, had met with three cases of post-operative mental aberration, two of which had occurred in old women after removal of the breast for cancer. The third case had occurred in a young woman who had had puerperal insanity prior to the operation. In two cases the insanity had lasted for three days, in the other for three weeks.

Dr. CARTLEDGE said that the question of post-operative insanity led us to discriminate as to the probable etiology in many of the cases. He thought the author of the paper had had it in mind to deal with those cases of post-operative insanity that were functional in character, rather than those in which there was suffering from the mental impression produced by the operation in general. He was quite sure that most of the cases, except those characterized by hereditary tendencies and traits, could be traced to some organic lesions. The history of the case should always be thoroughly investigated. He had encountered what he considered pure post-operative insanity in only two cases.

Dr. JOHN D. S. DAVIS considered the subject of interest from a medico-legal standpoint. No surgeon was absolutely free from such mental complications occurring in his operative work. He had encountered four cases. In a young man there had been no history of insanity, but an analysis of the urine had shown a great many casts and a slight trace of albumin before the operation. Operative interference had been followed by acute mania which had lasted seven days, then disappeared, and the patient had recovered. He expressed a desire that Dr. Wilson would, in closing, touch upon the responsibility of the surgeon in this class of cases.

Dr. JOSEPH TABER JOHNSON said that in talking with Dr. Kelly and Dr. Noble he learned that the latter had met with eight cases of insanity following perineal operations. He asked Dr. Wilson to state whether opera-

tions upon the perineum were more frequently followed by insanity than others.

Dr. WILSON said he had seen a number of cases of various forms of insanity following surgical operations, but did not think the disease occurred more frequently after perineal operations and operations upon the genitalia than after those upon any other part of the body. In reply to Dr. Davis's question, he did not think the physician was any more responsible for the death of a patient from insanity following an operation than he was for death from any other cause following any operation. He had never heard of a suit for malpractice having been brought against a practitioner for the occurrence of mental derangement from a surgical operation.

## SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

*Meeting of October 14, 1896.*

The President, Dr. R. C. NEWTON, in the Chair.

*(Continued from page 724.)*

**The Early Recognition of Uterine Cancer, with some Remarks on its Treatment.**—Dr. WALKER read a paper on this subject. (See page 834.)

Dr. GEORGE H. MALLETT said that every one appreciated the importance of early recognition of cancer, especially as the figures showed that the disease was on the increase. At the cancer hospital fully ninety per cent. that entered were past the operative stage, and the records showed that of the patients operated upon, the majority soon had a recurrence. The result of the operation would depend on the early recognition. He spoke of a theory advanced by Dr. Johnson, of Cincinnati, as to the causation of cancer—that the whole fault was in the trophic nerves; the nerve centres were out of gear, and failed to furnish the necessary nutrition; that the cancer growth was embryonic, and the cells had returned to that condition when the nerve supply was faulty; that in every case of cancer there had been some severe nerve strain, and he cited General Grant's as an instance. Of late years, heredity had been worked up a good deal. The speaker thought one of the most important early symptoms of cancer of the uterus was a slight flow of blood following coition. Last winter he had presented to the society a specimen of a carcinomatous uterus which he had removed, of which that had been the only symptom. The disease had now recurred and the woman would soon die. The uterus was affected much more frequently than any other organ in women, and more frequently in married women and those who had had a great many children. Carcinoma of the cervix was easy to recognize. An "operable" case was one in which neither the bladder, corpus uteri, nor vagina was involved, and the uterus not fixed. Irregular hemorrhage, a watery discharge, and pain were the usual symptoms, but the pain did not occur until too late. In most of these cases there was a lacerated cervix, and it had been proposed that every family physician should examine a patient two or three months after he had delivered her, and if there was a lacerated cervix have it operated on. Women who had cancer in their families should be carefully watched. Where there was any suspicion, he thought the only safe way was to excise a small portion and submit it to a pathologist.

Dr. NEWMAN spoke of three cases in which slight

hæmorrhage had followed coition, and, on microscopic examinations, a diagnosis of cancer had been made. He spoke of two cases sent to the hospital, one of which had been sent there for carcinoma, and had proved to be a bilateral laceration, and the other, diagnosed as bilateral laceration and infiltration of the broad ligament of the left side, which had proved on examination to be cancer, showing that the general practitioner often failed to recognize symptoms of cancer and simple pathological conditions of the cervix.

Dr. CORWIN spoke of a case that he had examined, illustrating that women did not always apply until the disease was too far advanced to permit removal. This woman had come to him stating that she had had slight pains for three or four weeks about the womb, with moderate hæmorrhage; she was about fifty years of age, in robust health, of an excellent color, and of good vitality. Examination had shown that she had cancerous trouble, affecting not only the cervix of the uterus, but also the anterior vaginal wall, and that it was beyond surgical aid. The symptoms calling for medical aid had been slight pains about her pelvis. She had rather suspected some disease, as her duties as matron of a hospital had made her suspicious.

Dr. RUPP said he would like to put two questions to the gynecologists present concerning operative procedures: First, in view of the fact that every woman who had given birth to a child had more or less laceration of the cervix, should such women be operated upon on that account in order to head off cancer of the womb? Second, those of us who did not operate, but whose opinion was asked concerning the comparative merits of operations, what were we to say as to cutting *versus* cauterizing operations? The results from Byrne's method seemed remarkable and encouraging.

Dr. WELLS said that in connection with the slight spotting after coitus, there was another symptom—viz., morbidly increased sexual appetite—and he spoke of a case that he had seen two weeks ago where there had been this symptom. The woman had been of rather spare build, and had been feeling a little below par; there had been no hæmorrhage, but a little spotting after coitus, and on examination the speaker had found a carcinoma. He spoke of statistics on cancer published by Roger Williams, of England, showing that in 1840 the mortality from cancer had been one in one hundred and twenty-nine; in 1894 the proportion had increased to one in twenty-three. He thought this enormous increase had been in part due to more careful diagnosis and more care in the registering of deaths. Roger Williams thought cancer was more frequent in luxurious countries, where a large amount of meat was consumed, than in countries where people lived a simple life. As to heredity, he knew of a family where, for five generations, from two to five members of the family had died of cancer—that was, in every generation the major part of the members had died from cancer.

Dr. RUPP asked if food had had anything to do with it in that case.

Dr. WELLS stated that the family had been well off, and had had enough to eat; he did not say that this proved carcinoma to be hereditary, but it was a remarkable instance.

Dr. YEATMAN WARDLAW said, in reference to Dr. Byrne's method, he thought the important thing in an operation was the entire extraction of the diseased parts, and he did not believe in the cauterizing method, which could not extend into the ovaries and tubes, or

along the lymphatics. He spoke of a case that he had seen where the uterus had been extracted, but, owing to a defect in the operation, the left ovary had been left in place. Three years after the disease had appeared exactly in the site of the left ovary. There had been no laceration of the cervix. The patient had had a number of abortions, but the cancer had been a superficial epithelioma. He spoke of a case that he had seen in which the patient had been to several physicians before she had come to him. The cancer had advanced too far to be operated on. Since that time she had had several physicians, and all but one of them had said that her disease was not cancer. She had died recently, and he had been told that the physician attending her had said she had "stomach complaint" which had "ruptured the bowels." This case, which had presented a typical clinical picture of uterine carcinoma, had been verified by a microscopic examination by one of our best-known pathologists, and was evidence that some physicians were at least careless in their observations.

Dr. WELLS agreed with the previous speaker that the operation by the cautery ought to be condemned, except in "inoperable" cases. The best operations were those which removed the greatest amount of tissue, where not only the uterus was removed, but as many of the adjacent lymph nodes as possible.

Dr. E. PIERRE MALLETT thought that some credit should be given to Dr. Byrne for his work in this line. The operation was not only the amputation by the cautery knife of the diseased or suspected tissue, but also a cooking or dry roasting of the adjoining tissues. In cutting with the knife, all of the lymphatic channels were opened, and carcinomatous cells could penetrate into adjacent structures, whereas in this operation the influence of the heat extended considerably beyond the limits of the incision and destroyed these cells, so that even if it was not possible to remove and destroy all of the diseased tissue, the patient was at least given a period of immunity from recurrence which no other record could show. Dr. Byrne reported cases (forty recoveries out of sixty-five) in which the patients had been free from recurrence from two to twenty-two years, or an average of nine years for each, while Dr. Polk reported fifty cases treated by complete hysterectomy, of which he said "every one relapsed within two years," and Dr. Mundé twenty-five cases, of which he said "invariable recurrence within six to nine months." He did not think one should condemn an operation which evidently was not thoroughly understood and had not been seen. Dr. Byrne's work in this direction had not received due recognition.

Dr. NEWMAN spoke of seeing a patient two years ago operated on by Dr. Byrne. The patient at the present time was entirely well.

Dr. GEORGE H. MALLETT said that, so far as statistics went, Dr. Byrne's method seemed to have the advantage over hysterectomy. He had absolutely no mortality with his operations; he had done from sixty to eighty operations without any shock or any bad symptoms whatever, and he had had patients who had been free from the disease from nine to twenty-one years; whereas, taking the operations of eighty-four physicians in New York, the average time of recurrence was two years, and a case in which the speaker operated lately had recurred in six weeks.

The PRESIDENT thought these results were too good to be true. Speaking of the conservatism of the English, some of their writers thought it was better to leave

cancer of the uterus alone, and also cancer of the breast; and stated what seemed to us rather strange, that removals of both organs had done more harm than good in the long run. At least, Sir Benjamin Brodie was reported to have said, after he had removed five hundred cancerous breasts, that he would never remove another without telling the patient that the operation would probably not prolong her life.

Dr. WALKER thought that the object was removal of diseased tissue, and did not see how cauterizing was any better than the knife. He thought the case reported by a previous speaker, where the ovary had been left, showed that complete extirpation would have been the better method.

The PRESIDENT thought it was not always easy to make the diagnosis, as there might be irregular hemorrhages and all the symptoms that had been mentioned in cases that were not cancer. He spoke of a case of enlarged tonsil he had treated lately. He had advised having the growth removed, but the patient would not consent. Then he had sent him to Dr. Delavan, who had advised putting him on the use of iodine for a week, and then having him examined again, as Dr. Delavan had strongly suspected a sarcoma or epithelioma. At the end of a week Dr. Delavan had removed part of the growth and had submitted it to Dr. Hodenpyl, who had pronounced it very difficult to diagnose the disease; there had been some indications of sarcoma, while in other places there had been areas of dense fibrous tissue which had suggested the possibility of tuberculosis or syphilis, but he did not find the typical bacilli of the latter disease. He had also noted certain appearances which had led him to suspect actinomycosis. He had concluded that it was probably a case of chronic hyperplasia of the tonsil. A few hours later Dr. Hodenpyl had sent a note stating that he had submitted the specimens to Dr. Prudden, who had thought there were indications of sarcoma. If the tonsil began to grow, that would settle the diagnosis. If, then, there was so much doubt in the minds of these excellent microscopists as to the true diagnosis in this apparently not difficult case, it was certain that in many cases of incipient carcinoma uteri the microscopist would be unable to settle the diagnosis.

Dr. WALKER said that the point he had wished to make in his paper was, that when a patient consulted a physician with symptoms which aroused his suspicion, he should sift the matter as far as possible, and after an examination, if he found anything suspicious, he should get specimens from the cervix or uterus and have a microscopical examination made. With reference to Dr. Byrne's method, he thought it was merely a question of removing the tissue; he did not see how the cautery would penetrate farther than the knife. He had no objection to any method that could remove sufficient tissue, and thought that best which did this in the safest way. As to laceration of the cervix, he thought one sometimes found a suspicious appearance about the cervix without any other symptoms that would lead one to suspect cancer. One should watch all suspicious cases very closely. The large increase in the death-rate from cancer was probably due to the fact that at the present time a more correct diagnosis was made. He asked how many deaths would be found occurring in 1870, for instance, from perityphlitis, and yet there must have been many cases of perityphlitis at that time, but they were not recognized.

## Miscellany.

**The Subcutaneous Employment of Sterilized Salt Water in Intestinal Affections of Nurslings.**—The *Presse médicale* for November 28th publishes a report of a recent meeting of the Société médicale des hôpitaux at which M. Barbier and M. Derooyer gave an account of some experiments they had made with this artificial serum in order to establish especially the modifications of the temperature and of the pulse. The serum which they employed was composed of a seven-per-cent. [seven-per-mille?] solution of salt water. The injections were made under the skin of the lateral region of the abdomen. The doses employed were somewhat varied, but never exceeded thirty cubic centimetres in twenty-four hours—that is, fifteen cubic centimetres in the morning and fifteen at night. The physiological effects were as follows:

Elevation of the temperature was observed to be almost constant, with some variations; this constituted, with the acceleration of the pulse, one of the normal symptoms which occurred in the period following the injections which the authors called the "time of reaction." This elevation of temperature varied from two tenths to eight tenths of a degree centigrade for each injection. It was appreciable half an hour after the injection, much more distinct after two hours, and perceptible almost in the same proportion three hours after, although often the deviation observed three hours afterward would be the same or inferior to that observed two hours afterward. This seemed to indicate that the period of "ascending reaction" did not go beyond the third hour after the injection. Five hours after the injection, in fact, the temperature often varied and was sometimes lower than that of the third hour. From this moment the temperature tended to become lower again. In fact, seven hours afterward, at the moment when the second daily injection was practised, the temperature chart showed a constant fall. In certain patients who probably presented more symptoms of poisoning the period of reaction was shorter, and in them the authors had employed three injections a day instead of two.

The thermic reaction was not observed with the same distinctness in all the patients. In those who were not very much poisoned the reaction was the most distinct; on the contrary, when death was imminent or the children were in a state of collapse, the reaction was much less appreciable. It might be, perhaps, said the authors, the ground for an immediate unfavorable prognosis if the reaction was insufficient or there was none at all, and an indication for repeating the number of injections. The reaction of the temperature which was observed, whatever might be its condition at the moment of injection, was as follows: Hypothermia, normal temperature, and hyperthermia.

The modifications of the pulse were parallel to those of the temperature. They consisted in an acceleration of the cardiac pulsations, which became at the same time fuller and stronger. This acceleration averaged about twenty pulsations.

The modifications of the general condition seemed to result from the stimulation of the entire organism by the injections, and in particular from the elevation of the blood pressure and of the temperature. The patients who were in a state of collapse, with cold extremities, seemed to come out of this condition: the ocular reflexes reappeared, the face resumed its natural color, and the

extremities became warm, all of which indicated a greater activity of the peripheral circulation.

The authors believed that these injections were indicated in the following circumstances: 1. In acute infectious enteritis with hypothermia, which did not expressly indicate, in consequence of an excessive diarrhoea, large injections of salt water. 2. In chronic enteritis which presented the same characteristics of hypothermia with progressive weakness. The authors thought that these injections were not indicated in the febrile forms, in which it did not seem called for to increase the elevation of the temperature or the acceleration of the pulse. But they were indicated when, during the course of a febrile diarrhoea, a period of hypothermia or collapse supervened.

These injections had no action at all on the diarrhoea itself or on the symptoms other than those of collapse, etc., due to the presence of toxic matters in the intestine. In regard to their action on the general nutrition, it was very doubtful if there was any at all. The authors noted in certain patients who were thin before the administration of the injections a stationary condition of the weight or even a slight increase.

**The "Trinity of Therapy."**—In the December number of the *International Journal of Surgery*, Dr. Thomas Osmond Summers remarks that if there is anything that distinctively marks the medical era which closes with the nineteenth century, it is the profound revolution in therapy. The former system, which was adopted from the natural tendency of the human mind to rest in experimental, yes, even empiric theory, based itself upon the direct action of remedial agents in disease without any reference to the action of such a remedy under the normal conditions of the organism. This system, recognized as the pathological system in contradistinction to the physiological method, necessarily called for an infinity of therapeutic agents, each one of which acted, or was supposed to act, independently of the others, to bring about a restoration to normal function and even structure.

As, however, bacteriological science has demonstrated the most wonderful principle of direct physiological antagonism to disease as its germs float through the blood current, thus proving the possibility of the organism to destroy its own enemies, modern therapeutics has lined its forces to support this grandest of all principles of resistance to disease in general.

There is, first, says Dr. Summers, a condition of the organism which is entirely dependent upon the support or sustenance of organic elements and conditions. To this are relegated entirely those remedial agents which are active in the support of such tissues as can receive nutriment only from a previously prepared substance. Second, there is a class of remedial agents that act by direct absorption, being distinctly elements of the organism as such, going in and passing out unchanged. This class represents the full power of inorganic therapy. They need no digestion; they require no physiological manipulation. They are arranged so as to be in perfect rapport with the functional activities of the organism and produce their effect *de novo*. Third, there are those agents which are distinctively absorbent in their character; they change the specific gravity of the blood and thus regulate its density or osmotic relation to nutrition and waste. How large a pathological field this covers will be readily discovered by the practical clinician.

Now, continues Dr. Summers, to meet these three great therapeutic principles, physiologists and chemists

have, for the past decade, bent their best efforts. It has been found, first, that there is a principle of peculiar power in the bean, which thoroughly supports the nerve and osseous organisms, while at the same time it sustains and stimulates the general cellular activity of the body. In all tropical countries this has long been known and therapeutically applied, although to this day they do not recognize the wide range of therapeutic power which this substance controls. The whole philosophy of its action lies in its vegetable albumin, and Dr. Victor Vaughan most certainly struck the keynote of vegetable therapy in using for his nuclein the yeast product which is so closely assimilated to the organism. Second, there are certain inorganic constituents, such as the phosphates, which enter the organism directly, perform their nutritive function, and pass out unchanged. Third, there are saline constituents of the organism, which resist the occurrence of excessive waste in the body. They regulate the amount of urea discharged or formed and control the balance of the waste and repair.

All of these principles have been met fully by the modern method of pharmaceutical science. The first in extraction of phaselin; the second in the chemical combination of rheumagon, and the third in the strong phosphatic product, the triumph of modern chemistry, to which, for some reason unknown, the name melachol has been given; but without doubt these are, says the author, the trinity of therapy.

This trinity of therapy is distinctively represented by the normal therapeutic agents which cover the physiological division of the organism. First, the fibro-areolar tissue, which is the groundwork of the organism upon which all of its structures are built. Second, the nerve tissue, which controls the distribution of nutrition and regulates the balance of function in the organism. Third, the digestive principles, which furnish the material for structure and the stimulus for function.

They are the necessary constituents or the proximate principles of the body, and without them it would starve, shrivel, decay, and die. As an example of this, says Dr. Summers, it is necessary only to refer to chloride of sodium, the deprivation of which would produce as certain death as a rifle ball through the heart. It is, therefore, the province of therapy to provide proper and assimilable combinations of those inorganic materials.

**The Treatment of Uræmia by Phlebotomy followed by Large Injections of Artificial Serum.**—In the *Union médicale* for December 5th M. H. Richardière says that the good results obtained by the method called lavage of the blood in the treatment of infections have led to the general employment of large injections of saline solutions or of serum, and their application in a rather large number of diseases.

These injections have been employed with success in the treatment of a certain number of toxic diseases. In uræmia, in which they are particularly indicated, it seemed at first that they could not be prescribed, because of the lesions of the kidneys and on account of their impermeability. It has been recognized since then, says the author, that the integrity of the kidneys is not an indispensable condition to the employment of lavage of the blood. Its efficacy in the treatment of uræmia is not, however, admitted by all authors. Lépine, in particular, states that he did not obtain recovery in several cases of uræmia in which large injections were employed.

Other authors, however, have been more successful. Sahli, who was the first to conceive the idea of employing lavage of the blood in uræmia, saved by this treat-

ment a patient who was in imminent danger of death. Bosc also recognized the good effects of subcutaneous injections of artificial serum in a case of uræmia due to parenchymatous nephritis. The patient recovered in four days.

M. Richiardié recently employed these injections in two cases of uræmia, one of which was very serious, and the results obtained were sufficiently favorable, he thinks, to justify the employment of this treatment.

A fact to be remembered, he says, in order to appreciate the treatment of uræmia by these injections is their perfect harmlessness. They are, of course, somewhat painful, but if they are administered aseptically they do not cause any local inflammation. The two patients referred to, in whom M. Richiardié tried the injections, had anasarca, but, although the injections were thrown into œdematous tissue, they did not cause any local symptoms.

The action of these injections is manifest on the temperature. In Bosc's patient the temperature rose a degree in an hour after the injection. In the first patient treated by the author the temperature also rose a degree during the day after the first injection; after the second injection it rose a little more than two degrees. In the second patient the rise in temperature was even more marked.

The pulse, which had been very rapid, became slower; the respiration, which had been irregular, of the Cheyne-Stokes type, became regular. The quantity of the urine passed during twenty-four hours increased notably.

Diarrhœa, says M. Richiardié, should be considered a favorable symptom in uræmia. It favors the elimination of the toxic matters which are the cause of the uræmic symptoms. It then constitutes an important element in the lavage of the blood.

The conclusions are: The elevation of the temperature, the diminution of the number of the pulsations, the regularization of respiration, the increase of diuresis, and diarrhœa are the important symptoms which follow the large injections of artificial serum in uræmia.

These symptoms are all favorable in connection with an intoxication. They fully justify the employment of the method called lavage of the blood, and explain the recoveries sometimes produced in cases which appeared to be hopeless.

**Senile Alterations of the Middle Ear.**—At a recent meeting of the Congrès international d'otologie, a report of which appears in the *Revue internationale de rhinologie, d'otologie et de laryngologie* for October, M. Ferreri stated that he had made investigations in order to determine if the deafness of old persons was due to a hyperplastic otitis media and its consequences, or rather to a process of involution. He examined two hundred and one old persons, nearly all of whom were over sixty years of age. He cited the opinions of Haller, Burdach, Boerhaave, and Mantovani, according to whom the deafness of old age depended upon alterations of the middle ear; and those of Kramer and Bonnafont, who attributed this deafness to the diminution of the powers in general, and consequently that of the hearing.

In old persons there might be observed a slight or complete deafness. In the latter case it was more frequently due to an affection of the nervous terminal apparatus or else to a lesion of the labyrinth, more rarely to a lesion of the trunk of the acoustic nerve, of the nuclei, or of the centre. The affections of the labyrinth were more frequent in old persons than in those of middle

age. The deafness of old persons from primary lesions of the acoustic nerve, in its labyrinthine terminations, was so rare that M. Ferreri, in his examination of the two hundred and one subjects, did not observe it once. Somewhat more frequent were the lesions of the acoustic nerve following the chronic affections of the middle ear.

With regard to the functional examination of the acoustic nerve, M. Ferreri came to the following conclusions: 1. In old persons the transmission of sound by the bones is accomplished preferably through the right ear. 2. Aerial transmission is preferably by the left ear. 3. Out of the two hundred and one subjects, twenty-one only had no lesions of the labyrinth. 4. The subjects seemed to hear the ticking of a watch better than a whisper. 5. In a given number of old persons the majority of them had healthy ears. 6. In men the left ear was more frequently diseased, and in women the right ear.

M. Ferreri concluded that the causes which determined this deafness in old persons were as follows: The accumulation of wax; hyperplastic otitis media; the remains of purulent otitis media; chronic purulent otitis media; and, rarely, lesions of the auditory nerve.

**The Effects of Bicycle Riding on the Perinæum.**—In the *Gazette hebdomadaire de médecine et de chirurgie* for December 6th there is a long and interesting article on this subject by M. E. Aldhuy in which the author deals with the lesions of the perinæum produced by the bicycle saddle, the action on the urethra and on the *bas fond* of the bladder, the action on the external genital organs, and acute traumatism of the perinæum and their ætiology. He draws the following conclusions: 1. The injuries produced by the bicycle to the perinæum are of a grave and various nature. 2. Certain lesions of the perinæum have been observed, such as cutaneous erythema, abscesses, hæmatoma, etc., and finally, a more or less profound anæsthesia caused by repeated pressure. 3. There have been observed also certain functional troubles, such as the retention of urine often seen in men and undue frequency of urination in women. 4. The existence of urethritis from pressure of the saddle is not demonstrated, but it is certain that chronic inflammation of the canal and certain inflammatory complications, such as urinary abscesses, etc., may be produced or aroused by the bicycle. 5. Sometimes the venous arrest due to the compression of the perinæum provokes erection, although this is rare; more frequently, on the contrary, the continual perineal massage of the saddle produces temporary impotence. 6. With regard to genital excitation in women, it has certainly been much exaggerated. The bicycle has not the inconveniences of the sewing-machine. 7. The majority of cases observed up to the present time have been due to a bad posture or to a defective saddle. 8. The real accidents to which bicyclists are exposed are traumatic in nature, and are produced by jolting over uneven roads, which throws the rider forward on to the end of the saddle; they are also caused by falling on the rear wheel or on the framework. These falls are not very serious; sometimes a slight tear of the urethra may be observed, but they are cured rapidly without the least complication. In a very curious case, to which the author refers in the beginning of his paper, a fall on the wheel caused an enormous hæmatoma of the perinæum and of the scrotum. The bloody tumor increased and the patient presented symptoms of internal hæmorrhage. M. Poncet, says the author, ascertained the integrity of the canal by means of a catheter. A very large incision was

made in the centre of the mass, which enabled him to discover a tear of the transverse artery of the perinæum. The hæmorrhage was arrested with a ligature. 10. More frequently, however, the urethra is involved, and sometimes completely ruptured. In this case all the complications which follow rupture of the canal may be observed. 11. As the section of the urethra is here ordinarily very distinct, suture of the two ends may be followed by union by first intention. M. Poncet obtained very remarkable results in a case in which, seven years after a complete rupture of the perineal urethra, the patient did not show the least symptoms of stricture.

**A New Pathology of Jaundice.**—A correspondent of the *Lancet* for December 5th says that according to the new theory of jaundice suggested by Dr. Pick, and described by him before the Vienna Medical Society, the cause of the disease is to be sought for in the liver, where the bile is formed, and consists in a disturbance of the function of the liver cells. These cells have the remarkable selective property of discharging bile into the bile capillaries only, while both urea and sugar pass into the blood. This function, however, may sometimes be disturbed, with the result that a part of the bile is discharged into the lymph capillaries. Dr. Pick has given the name of paracholia to this disturbance, which he considered may be caused either by abnormal irritation of the secretory nerves of the liver (nervous paracholia) or by toxic substances (toxic paracholia). The toxic substances may be either poisons introduced into the organism from without, or, on the other hand, they may be produced by bacteria, whether those of the intestine (paracholia by self-intoxication) or pathogenic microorganisms (paracholia by infection). The jaundice of bilious colic is an instance of nervous paracholia, the jaundice of the newborn infant is a case of paracholia by self-intoxication, as it is, in Dr. Pick's opinion, due to the influence of toxins generated in the intestines in consequence of the taking of food. Catarrhal jaundice is an example—and, in fact, the most remarkable one—of paracholia by infection; it may, therefore, be regarded as a zymotic disease of the intestine. In the discussion which followed, continues the writer, Professor Basch remarked that jaundice might arise from engorgement of the bile passages. Dr. Pal, while agreeing to some parts of Dr. Pick's theory, said that no secretory nerves had hitherto been found in the liver, whereas, according to Vulpian, irritation of the nerves passing from the celiac plexus to the liver caused a change in the color of the gland. Dr. Pal himself had proved that an effect might be produced on the liver vessels by the splanchnic nerves; the liver had only vasomotor nerves, not secretory nerves. Dr. Pick, in his reply, stated that the bile when secreted exerted a pressure equivalent to two hundred millimetres of water, and that, according to Heidenhain and other authors, the existence of secretory nerves in the liver was to be presumed.

**A New Treatment of Hip Disease by Arthrotomy, Scooping of the Head and Neck of the Femur, and Trans-trochanteric Drainage.**—The *Revue de chirurgie* for November 10th contains a report of the Congrès français de chirurgie, at which M. Delagenière stated that he had adopted the following technics: An incision similar to Langenbeck's was made, but extending farther down on the thigh, to about two centimetres below the base of the great trochanter. This incision should measure about fifteen centimetres. The fibres of the glutæus maximus

were separated in order to penetrate as far as the pelvic-trochanteric muscles; the pyramidalis and the glutæus medius were separated and an incision of the periosteum was made from the acetabulum as far as the base of the great trochanter; this included the internal and external surfaces of this bony prominence. The articular capsule was opened by a T-shaped incision in order to permit of exploration of the articulation. Afterward the periosteum on each side of the incision was detached in order to make the operation subperiosteal. The upper border of the great trochanter was excised as far as the upper border of the neck; with a gouge-forceps the neck was hollowed as far as the head; afterward the head was scooped and a portion of the articular cartilage was removed.

Finally, the treatment terminated in scooping of the great trochanter, which M. Delagenière followed to within a centimetre of its base in order to establish a regularly dependent passage following the direction of Merkel's spur. The soft parts were then united above the hollow passage, after a metallic tube had been laid in the bottom of the passage, the outer end of which was attached to the skin. This drain should be left in place until the patient recovered.

M. Delagenière stated that he had practised this operation twice in cases of very grave suppurating coxalgia, and the two patients had made a rapid recovery.

The conclusions to be drawn from these facts, he said, were the following: 1. The operation was simple and easy. 2. It did not seem to be of a serious nature. 3. Drainage of the diseased articulation and of the epiphysis was obtained definitively. 4. The hip preserved its shape and part of its movements.

M. Calot thought that coxalgia should be cured without lameness. Contrary to former opinions, this disease was scarcely ever fatal; it was not really serious except when secondary infections supervened. It was not correct to maintain that coxalgia which had been cured always left indelible traces in the shape of a very awkward lameness. At the present time the mobility of the limb might be preserved in a great majority of cases.

In order to obtain this result, it was necessary for the surgeon to keep his patients under daily observation from the first stage of the disease. The surgeon was responsible, he thought, for the bad attitudes that might be taken by the limb; they only were the cause of the lameness. M. Calot stated that a patient who was cured of coxalgia, with a shortening of two centimetres, and even stiffness of the hip, would eventually be able to walk without showing any pronounced lameness, if the muscles were strengthened by massage, and if he was taught to walk.

The great majority of patients who were cured were left with an insignificant shortening of the limb, with a scarcely noticeable atrophy, and preserved some movements of the articulation. M. Calot had even seen in two cases the entire restoration of the movements of the articulation, after suppuration of the articular cavity.

On the whole, against the grave defects of lameness, defective attitude, and iliac subluxation, we had a potent remedy in immobilization by means of plaster of Paris. Above all, resection should not be practised.

**Salol in the Treatment of Acute Angina in Children.**—In the *Journal des praticiens* for December 5th M. de la Carrière remarks that the internal employment of salol in angina has given excellent results, and that he has prescribed it in cases of amygdalitis, acute angina, and non-diphtheritic cases, whatever might be their

cause. It is a general antiseptic and analgetic with an elective action on the pharynx. It quiets the pain and the dysphagia almost immediately, it brings about a rapid relaxation in the physical symptoms, it prevents the formation of abscesses, and it always shortens the duration of the disease, especially if it is administered in the beginning.

The daily amount for an adult is sixty grains. For children the adjustment of the dose is easy, as salol is always well borne, for trouble with the kidneys, which is the only contraindication, is exceptional in them. The amounts to be taken daily are as follows: For children a year old, eight grains; for children two years old, fifteen grains; for children three years old, twenty-three grains; for children four years old, thirty grains; and for children eight years old, forty-five grains. This amount is sufficient until the age of fifteen, when it may be increased to sixty grains without inconvenience, if necessary.

With regard to the mode of administration, M. de la Carrière recommends the following formula:

R Salol .....	30 grains;
Sweet almond oil,	
Gum arabic .....	60 "
Syrup .....	450 "
Distilled water .....	2.5 ounces.

Peppermint, orange-flower water, vanilla, or cherry-laurel water may be added to make it aromatic.

This quantity is sufficient for three doses during the day. Salol may be given at mealtime, as it does not disturb the digestion.

The employment of this drug should be suspended if the urine appears of a dark color. This coloration, which indicates the transformation of the carbolic acid in the organism into hydroquinone and pyrocatechin, is not to be feared.

In pronounced inflammatory angina, especially when there is danger of abscess, M. de la Carrière pushes the doses until the organism is well under the influence of the drug and saturation is evident. Moreover, elimination occurs rapidly, and when the normal color of the urine returns it is rarely necessary to have to renew the dose, and recovery is assured.

It is preferable to give salol in a potion rather than in capsules, for the saliva rapidly decomposes it. Each time the patient takes the potion there are formed instantaneously in the mouth carbolic acid and salicylic acid, which have a direct topical effect on the diseased parts. This local antiseptic bath is all the more pronounced and, consequently, efficacious, the more intense the disease, for, when deglutition is very painful, the potion remains for a longer time in the mouth, and contact with the drug is more prolonged.

A good way also, says the author, is to incorporate the salol in chocolate pastilles. For persons predisposed to angina of any kind the use of these pastilles is especially recommended as a preventive. During the cold and damp season these pastilles seem to diminish the sensitiveness of the throat by combating, the author thinks, the latent microbism of the tonsils which are in a more or less chronic state of inflammation.

**The External Application of Pilocarpine in the Treatment of Nephritis, and its Diuretic Effect.**—The *Lyon médical* for December 6th contains a review of a work on this subject by M. Emile Julia, in which the writer says that this method of applying pilocarpine has been known for two or three years. In 1894, M. Mollière, who was the first to discover it, recommended it after

having experimented with the treatment in his service at the Hôtel-Dieu.

This treatment consists in friction of the entire dorso-lumbar region with an ointment composed of three ounces of white vaseline and from three quarters of a grain to a grain and a half of nitrate of pilocarpine. The region is afterward covered with a layer of cotton or waxed linen which is held in place with bands of turlatin. The frictions are made every morning and the covering remains on during the day unless it inconveniences the patient too much. This, however, is very rare.

More than eighty patients with acute nephritis from the effect of cold, or infectious nephritis, or chronic nephritis were subjected to this treatment. Complete recovery occurred in the first set, and a rapid and lasting disappearance of the acute symptoms in the second was invariably observed.

A remarkable symptom observed in the majority of the cases was an energetic diaphoresis, which remained excessive in a large number of cases while the treatment lasted.

The albumin often disappeared from the urine and always diminished in these patients. At the same time elimination was effected with remarkable intensity and the symptoms yielded with the greatest rapidity, the œdema disappeared, the dyspnoea gave place to normal respiration, and the minor symptoms very soon passed away.

Numerous experiments have demonstrated the specific properties of pilocarpine employed in this way, and the results obtained should not be imputed to the cutaneous excitation produced by the frictions or to the heat caused by the layers of cotton.

The importance of this treatment in clinics, says the writer, may be seen. It is applicable to an affection which very often baffles the physician; it is, furthermore, carried out with a medicament which favors elimination without injuring the stomach. He concludes, therefore, that pilocarpine may give remarkable results and prove a valuable remedy in cases of nephritis.

**Mydrol.**—This name has been given to an iodomethylate of phenylpyrazol, which is a white, odorless, bitter powder readily soluble in water. It seems from experiments made under the direction of Professor Albertoni, of Bologna (*Thérapeutique Wochenschrift*, December 6, 1896), that mydrol dilates the pupil in animals that have a round pupil, but has no such effect on those in which the pupil is oblong. Dr. Cattaneo, of Professor Tartuferi's clinic, is cited as having found that, by reason of the short duration of its mydriatic action, when employed in a solution of from five to ten per cent., and its transitory effect on the accommodation and especially on the tonicity of the eye, its diagnostic use is of advantage in cases in which there is reason to apprehend harm from the increase of intra-ocular pressure caused by other mydriatics. Albertoni adds that it is absolutely unirritating and non-poisonous, and that it excels cocaine in diminishing the amount of blood not only in the vessels of the conjunctiva, but also in those of the iris and most probably in those of the deeper structures. By virtue of these properties, while it has no actual anæsthetic action, it is serviceable in ciliary and supraciliary pain, blepharospasm, lachrymation, and many diseases of the iris, the cornea, the sclera, and the conjunctiva, especially that of the globe. Mydrol is said to be absorbed rapidly and to be eliminated unchanged in the urine.
